The Henri Seibert Award was initiated in 1992 to provide recognition for the best student papers given at the annual meeting of the SSAR. To be eligible, the presented paper must be the results of research conducted by the presenter. The research must have been done while the student was in either an undergraduate or graduate degree program. The presentations will be judged by the SSAR student prize committee. One Seibert Prize of US $200 may be given in each of the following four categories: Conservation, Ecology/Evolution, Physiology/Morphology, and Systematics. Consult Herpetological Review 28(4): 175 for recommendations to students entering the Henri Seibert competition. Students entering the competition must be members of SSAR. Students can win the Henri Seibert competition only once. Please indicate the category to which you are submitting your abstract on the abstract form in the Call for Papers.

SSAR Student Awards Fundraiser: 2001 Results and Call for 2002 Donations

We are disappointed to announce that NO travel grants were awarded for the 2001 Indianapolis SSAR/HL meeting, because we received NO applications. The money raised will be rolled over to the Brazil meeting in 2003.

We thank all who donated items to the 2001 silent auction at Indianapolis: Mike Cardwell, Harold Dundee, Harry Greene, Julian Lee, Jacqualine Grant, Joseph Mendelson III, Bob Reed, Harold Cogger, Rick Shine, Karen Lips, Roger Birkhead, Arthur Echternacht, Auburn Herpetological Society, Paul Gritis, Peter Meylan, Chuck Crumly, Kraig Adler, Nicole Sloan, Ricardo Javier Torres Cervantes, Scott Boback, Breck Bartholomew, Norm Scott, Alan Savitzky, Barbara Savitzky, Katy Kyle, Jennifer Ferri, and to any we may have missed. The Seventh Annual Frameable Art Silent Auction at Indianapolis raised $1495.00 for future student travel awards. On behalf of the SSAR, thanks to all who helped, including Matt Williams and Matt Greene, Auburn University, Henry Mushinsky, and the University Place Conference Center and Hotel. Special thanks for a job well done to the SSAR STAC Chairman, Scott Boback.

The SSAR STAC announces the Eighth Annual Frameable Art Silent Auction to be held at the 2002 SSAR meeting at Kansas City. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *Glen Lubcke and John Campbell, Biology Department, California State University, Chico, California 95929, USA; e-mail: gmlubcke@pacbell.net; tel. 530-898-6303.*

SSAR Student Travel Awards Call for Applications

Awards of US $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award.

APPLICATIONS MUST BE POSTMARKED BY 15 MAY 2002. Award recipients will be notified by 1 June 2002 and award checks will be disbursed at the meeting. Direct requests for information to: *Glen Lubcke or John Campbell, Biology Department, California State University, Chico, California 95929, USA; e-mail: gmlubcke@pacbell.net or tel. 530-898-6303.*

Help Us Send You Undergrad Students

SSAR gets many requests from USA high school students regarding colleges offering coursework in herpetology as part of a biology-related degree. Many times, students are interested in remaining within their home state for undergrad degree work.

If you teach classes, and/or offer undergrads participation in research in herpetology, please e-mail the following to George Pisani (gpisani@ku.edu):

Institution name and address AND home page URL
YOUR name and contact info (e-mail, home page, postal address, phone/FAX)
Your research interests
Your class offerings

We'll try to match these with the interests sent by prospective students. While thus far we have not had such inquiries from outside the USA, we'll gladly incorporate ALL such info into the database in order to assist any who inquire.

2001 Annual Meeting: Indianapolis

The 44th annual meeting of SSAR took place from 27 to 31 July 2001 in Indianapolis, Indiana. This year's meeting was held jointly with The Herpetologists' League and was hosted by Henry Mushinsky and Indiana University-Purdue University Indianapolis (IUPUI). All meeting activities were conducted at the IUPUI University Place Conference Center and Hotel, an impressive and comfortable conference facility. More than 300 presentations, about two-thirds of them oral, were scheduled for twenty sessions held throughout the four days of formal meetings. Two symposia provided focused topical presentations. On Sunday, 29 July, "Herpetologcial Research in Zoos: The Academic Connection" was coordinated by Hugh Quinn and John Groves. This symposium was dedicated to the memory of the late Sherman A. Minton, Jr., and acknowledges the contributions Minton made to zoological park research on amphibians and reptiles, incorporating a collection of 20 talks from members of the academic and zoological park communities. "Amphibian Population Declines" addressed that topic in a two-day symposium (30–31 July) examining numerous issues related to amphibian population concerns. This symposium was organized by David Green and Karen Lips, supported by SSAR and The Herpetologists' League, and brought together experts in many areas to discuss research findings and conservation recommendations in a series of 32 presentations.

Social Programs

A variety of social events served as lively diversions from the daily scientific presentations. Friday, 27 July 2001, was a day reserved for the board meetings of the two societies. Friday evening marked the return of the SSAR President's Travelogue to the annual meeting. Slide presentations featuring regional amphibians, reptiles, and the people who study them were laced with humorous commentary. Presenters included Patricia Burrowes (Peurto Rico), Tim Halliday (South Africa), John Wilkinson (provided a world-wide herpetological perspective), Ross Alford (Australia), Hinrich Kaiser (Caribbean Islands), and Mike Lannoo (who proved beyond a shadow of a doubt that there are no amphibians or reptiles in Antarctica). Slide presentations were followed by a cash-bar social at the University Place Sports Bar, allowing attendees the opportunity to socialize at their leisure. The Opening Plenary Session, the morning of 28 July, opened with an introduction by Local Committee Chair Henry Mushinsky. David L. Stocum, Dean of the School of Science at IUPUI, greeted meeting attendees. To open the meeting, Kraig Adler and David Hardy made comments honoring the late Sherman A. Minton, M.D., a long-time supporter of SSAR and Indianapolis resident. The Herpetologists' League Distinguished Herpetologist Lecture was given by Bill Branch, Curator of Herpetology at the Port Elizabeth Museum, who spoke on "Herps and Hopes: Africa in a New Millennium." Following the Opening Plenary session, most attendees gathered in the courtyard of the University Place Conference Center and Hotel to pose and squint for the meeting photograph. This year's photo was included in the conference registration fee and attendants had the opportunity to pick up their prints during the latter half of the meeting.

On Saturday and Sunday, 28–29 July, meeting attendees had the opportunity to view and photograph an impressive assemblage of amphibians and reptiles native to Indiana. The live exhibit was organized by Daryl Karns and Dennis Brown of the Hoosier Herpetological Society and marked a welcome return of this popular aspect to the annual event. Also during these two days, SSAR sponsored the Silent Auction to raise funds to benefit student travel expenses. Scott Boback supervised and coordinated this successful activity that saw active bidding on numerous items of herpetological art, literature, and culture. Saturday evening culminated with an "Icebreaker" in the University Place Ballroom. Drinks, snacks, and light appetizers provided the catalyst for this social gathering. Sunday morning, early risers enjoyed a bird watching opportunity to Eagle Creek Park guided by Greg Watkins-Colwell. During the afternoon of 29 July, the release of a new two-volume SSAR publication resulted in much excitement and attention. The launching of the 2nd edition of "The Hylid Frogs of Middle America" by William E. Duellman, with many new watercolor renderings by David Dennis, saw the author and artist signing copies of this revised and updated herpetological classic. Additionally, original David Dennis artwork from the publication was available.

The evening of 29 July saw participants gathering under tents and on the lawn adjacent to the University Place Conference Cen-

A highlight of this year's meeting was the unveiling of William Duellman's *Hylid Frogs of Middle America*. A book signing took place, with author and illustrator (David Dennis) on hand to inscribe books. Shown here, from left to right, are David Dennis, Bill Duellman, Ronald Javitch (benefactor of this revised edition), and Kraig Adler (editor).

Bill Duellman was kept busy signing copies of his new book.

ter and Hotel for the Annual Barbecue. A variety of picnic side dishes complemented fried chicken and barbecued ribs. Following the meal, the annual meeting Auction was cosponsored by SSAR and HL with proceeds from the event being split between the two societies. David Morafka and John Moriarty conducted the auction with assistance provided by Ken Dodd, Julian Lee, and Craig Nelson. Active bidding on a variety of herpetological items carried activities well into the evening and provided significant financial support for this year's meeting.

Monday, 30 July, saw the return of the SSAR Herpetological Quiz compiled and organized by Marty Crump and Julian Lee. Monday evening provided meeting participants with the opportunity to view the latest versions of the David Dennis and Eric Juterbock slide presentations of regionally distinct herpetofauna, coupled with a historically oriented slide show by Dennis, Juterbock, and Kraig Adler. Always a visual and auditory treat, this year's installments pleased a packed crowd in the conference center auditorium.

Business Meeting and Board Meeting Summary

Society President David Green called the Annual SSAR Business Meeting to order at 1820 h in Room 118 of the IUPUI University Place Conference Center and Hotel on Monday, 30 July 2001. The Business meeting was well attended, with approximately 50 Society members present. The SSAR Board meeting was held on Friday 27 July 2001 at the Conference Center.

President Green summarized reports to the SSAR Board of Directors by focusing on several key issues. Concerning efforts to reach the international herpetological community through involvement with SSAR. To that end, membership brochures have been produced in Spanish, Portuguese, and French. A German version of the brochure is in the works. Regarding personnel changes within the Society, the pending resignation of Robert Aldridge from the Treasurer's position necessitated finding worthy candidates to this important Board seat. To aid in the search process, President Green appointed Julian Lee to head an effort to identify candidates. President Green proposed the possibility of splitting the duties of the Treasurer into two positions: A) the traditional financial tasks of the Treasurer and B) a Membership Secretary to coordinate membership efforts. President Green appointed Karen Lips to head up a nominating committee to seek candidates for the 2001 elections and appointed Julian Lee to do the same for 2002. During his first year in office, President Green (with Board approval) also appointed the following individuals to positions within the Society: Brian Miller – Caudata Section Editor for the *Catalogue of American Amphibians and Reptiles*; Breck Bartholomew – to take the post of Publications Secretary as of 1 October 2001 (to replace the outgoing Robert Aldridge). Green also announced that Steve Corn has requested a replacement editor be sought for *Herpetological Conservation.* All outgoing editors and officers were thanked for their thoughtful service to the Society.

The Board considered electronic publishing options for SSAR and joined with the HL Board in a special joint Board meeting session to hear representatives from Allen Press and Blackwell Science explain the options and answer questions. Acknowledging that electronic publishing, in some format, is an eventuality for the Society, the SSAR Board felt strongly that we should move the Society forward—electronically publishing its journal while also continuing to produce a paper version. As there are many pros and cons to be addressed with electronic publishing, including issues of generating revenues and organizational management, the Board did not debate at this time precisely how SSAR will embrace this technology. Instead, a joint Task Force with members of The Herpetologists' League, who are facing similar decisions, has been struck with a report on options expected next year.

Society Treasurer Robert Aldridge reported that SSAR remains financially viable with total assets of $219,000 in restricted accounts. Aldridge reported that the sale of SSAR publications totaled nearly $69,000. The appointment of Breck Bartholomew as Publications Secretary was announced and Breck noted that his responsibilities in this Society position would be separate and distinct from his personal enterprise as a book dealer. Bob reports that SSAR membership continues to remain stable, at 2384 for FY 2001.

Journal of Herpetology Editor Brian K. Sullivan (*in absentia*) submitted a report indicating a number of personnel changes. The addition of Jean Bann, as Copy Editor, to the *Journal* staff has helped in formatting electronic versions of submissions to Allen Press. Additional changes in the editorial staff include Stephen Busack, as Associate Editor (replacing the outgoing Aaron Bauer), and John Wiens (Editorial Board). Brian reported that submissions to the *Journal* were up slightly in 2000 from the previous year at 262. Of these submissions, 90 were accepted, representing a 34% acceptance rate. Submissions as of June 2001 were running 20% higher than a comparable date in recent years, and could reach record levels. Sullivan reported that publication lag times of 9–12 months could be expected for accepted manuscripts, noting that decreasing that time could incur significant costs for the Society. Sullivan endorsed several recommendations made by the Publications Task Force that had been chaired by William Cooper: 1) Changing the *Journal of Herpetology* to a glossy paper stock; 2) Increasing the font size of the *Journal* from its current 9 pt (for Article text) and 8 pt (for citations and Shorter Communications) to 10/9 pt (for text and citations in Articles) and 9 pt (for Short Communications). Sullivan estimated that increasing font size represents a potential increase in page numbers that would result in

added publication costs; and 3) Implementing the addition of abstracts to Shorter Communications. The Board approved the idea of adding abstracts to Shorter Communications and of moving to glossy paper as it would represent a minimal increase in cost to the Society for the increased "professional" appearance of the publication. However, the Board believed that more information was needed before deciding on the issue of increased font size for the *Journal of Herpetology*.

Herpetological Review Editor Robert Hansen reported personnel changes including the addition of Eli Greenbaum and Omar Torres as Section Editors (Current Research), and Chris Sheil as Index Editor (a new *HR* position). *Herp Review* seems to be able to maintain its current, expanded production size—272 pages in four issues for Volume 31—a 6% increase from Volume 30. Bob reported that the addition of a new Herpetological History section to *HR* has seen several submissions. Hansen noted that submissions can expect a lag time from acceptance to publication of 3 months (for geographic distribution notes) to 6–9 months (for articles and natural history notes). Bob also said that efforts to electronically index *HR* articles are being developed.

Robert Powell, Editor of the *Catalogue of American Amphibians and Reptiles* (*CAAR*), submitted a report on the status of this publication effort. Bob reported that the 2000 contributions to *CAAR* consisted of 20 accounts (Nos. 701–720; 7 salamander, 1 frog, 8 lizard, and 4 snake accounts), for a total of 80 printed pages. Color plates were included in 16 of the accounts. Bob expects the completion of 20 accounts for 2001 (with 17 of these having color photographs), has plans for another 20 accounts for 2002, and would like to see this number maintained annually, as long as sufficient number of individuals submit species accounts. Digital technology continues to be used to archive *CAAR* accounts on CD-ROM.

Kraig Adler (Editor), submitted reports on the activities of two Society publication series, *Contributions to Herpetology* and *Facsimile Reprints in Herpetology*. Recent publications include "Herpetofauna of New Caledonia and Surrounding Islands," by Aaron Bauer and Ross Sadlier (November 2000), "Herpetological Illustrations from the Spencer Research Library, University of Kansas," compiled by Sally Haines (December 2000), and "Hylid Frogs of Middle America," by William E. Duellman with new illustrations by David Dennis (July 2001 – see comments above). Upcoming and newly completed offerings include several significant publications. "Amphibians of Honduras," by James R. McCranie and Larry David Wilson is due in December 2001 and will feature accounts on 116 species from this significant Central American region. "Reptile Fauna of Ceylon," by William Ferguson is expected in December 2001. This monographic publication is the first systematic list of Sri Lankan herpetology and is being issued to commemorate the Fourth World Congress of Herpetology (December 2001 in Colombo, Sri Lanka). Also expected in late-2001, or early-2002, is a reprinting of "Anatomy of the Salamander," by Eric T. B. Francis. Originally published in 1934, this work will have a new introduction by James Hanken. Anticipated by mid-2002 is "Herpetology of Cuba," by Thomas Barbour and C. T. Ramsden. This reprint will include new text and additional photographic plates, with an introduction by Blair Hedges expected. Adler reported that three additional projects are in the works and should be published in the next year or two. These include "Field Guide to Amphibians and Reptiles of the West Indies," by S. Blair Hedges, "Lizards of Southern Africa," by William Branch and Aaron Bauer, and "Biology of the Reptilia, Volume 20 (Morphology)," edited by Carl Gans and Abbot Gaunt. Also anticipated by the summer of 2002 is a comprehensive index to "Biology of the Reptilia," by Ernie Liner. This will represent Volume 21 in the series and may be available in a searchable CD-ROM format. Adler reported that the transition of his duties as Editor of the *Facsimile Reprints* to Aaron Bauer has already begun, and he has complete faith that the series will be in good hands.

The annual barbecue afforded attendees opportunities for discussions in a more relaxed setting. From left to right, Steve Morey, Roland Knapp, Carlos Davidson, Norm Scott, and Dave Bradford contemplate amphibian declines in the American West.

Herpetological Circulars Editor John Moriarty reported on the status of three publications in that series. *Herpetological Circular No. 30* – "Amphibian Monitoring in Latin America: A Protocol Manual," by Karen Lips, Bruce Young, Jamie Reaser, and Roberto Ibáñez was expected in August 2001. This contribution is being produced as a bilingual publication (Spanish and English) with production costs being covered by a National Science Foundation grant to the Nature Conservancy. The authors will receive 300 copies for distribution in Latin America. *HC No. 31* – "Conservation Guide to the Eastern Diamondback Rattlesnake," by Walt Timmerman and Marty Martin is planned for 2002. "Herpetological Collecting and Collections Management, revised edition," (*HC No. 32*) by John Simmons will be a revision of *Herp Circular No. 16* and is anticipated for 2002.

Stephen Corn, Editor of *Herpetological Conservation*, reported that progress on Volume 2, "Ecotoxicology of Amphibians and Reptiles," has continued to see difficulties. A proposed Volume 3, "Conservation and Status of Reptiles in Canada," has received solid backing by The Canadian Amphibian and Reptile Conservation Network. The lead editor for the publication is Carolyn Seburn, who has promised reviewed manuscripts, but Corn reports that this volume likely will not be ready until 2002. Other projects are in the planning phase, but will require the direction of another editor as Corn has requested to be relieved of this duty.

Brian Crother (Chair), on behalf of the Standard English and Scientific Names Committee, reported that the completion and publication of *Herp Circular No. 29* was a successful endeavor. The Board recommended that this publication should be recognized as the accepted reference for nomenclature of amphibians and reptiles in North America. President Green stated that this point has been acknowledged by ASIH and HL, and that it had also been accepted by Canadian herpetological organizations.

Fearless Dave Morafka once again demonstrated his willingness to sell just about anything, as evidenced by this attempt to auction old luggage.

Mike Plummer, Chair of the Conservation Committee, reported that the committee continues to focus on informative efforts. To date, 32 of 50 U.S. state agencies have contributed material to the SSAR Conservation Website. Members of the committee include Kurt Buhlmann, Ken Dodd, Mike Dorcas, Lee Fitzgerald, John Jenssen, Andy Price, Steve Sheffield, and Mike Sredl. Other efforts for the year consisted of sending a position letter to the U.S. Fish and Wildlife Service (USFWS) supporting a "Threatened" listing under the Endangered Species Act for the Chiricahua leopard frog, *Rana chiricahuensis*. A second position letter to USFWS was submitted supporting an "Endangered" listing under the ESA for the Mississippi gopher frog, *Rana sevosa*. The committee also endorsed a letter-writing campaign, to Congressmen, supporting the Conservation and Reinvestment Act (CARA) in several states. A letter from the committee to Mr. Abe Blank praised the education and conservation efforts through his El Serpentario y Centro de Educacion Medio Ambiental de La Paz. Mr. Blank's serpentarium was a featured destination during last year's meeting in La Paz, B.C.S., Mexico. Sadly, Mr. Blank was killed in the months following the 2000 meeting, under mysterious circumstances.

Membership Committee Chair Theodora Pinou reported that several initiatives aimed at increasing SSAR membership have been investigated and implemented. Pinou outlined several strategies: 1) Active recruitment at regional and local herpetological meetings. Whenever possible and appropriate, Pinou would like to know about and assist with membership recruiting efforts. Associated with these membership activities, Pinou has worked with other Society members to identify areas that will result in increased foreign membership. Spanish and Portuguese versions of the online membership form are available. Electronic membership capabilities would be of significant benefit, not only to international members, but also to the Society at large. Primary concerns are related to website security and electronic maintenance of memberships. 2) An alternative membership dues structure for international members. The possibility of lowered dues for international members was discussed, but no solid recommendations were made in the face of increased postal rates and operational costs. 3) Direct solicitation of invitations for membership from individuals identified from the "Combined Directory of Herpetologists" that did not indicate SSAR membership. Pinou reported that it is difficult to gauge the effectiveness of this effort, but stated that 11% of contacted individuals subsequently joined the Society. Future efforts of the Membership Committee will attempt to identify the origin of members' registration to target effective strategies.

Several outstanding student projects received recognition during the past year. Robert Gatten reports that the Kennedy Award Committee selected the best student paper, from 10 eligible contributions published in 2000. The committee selected "Nest site selection, larval hatching, and advertisement calls of *Rana arathooni* from Southwestern Sulawesi (Celebes) Island, Indonesia," by Rafe M. Brown and Djoko T. Iskandar (*Journal of Herpetology* 34:404–413) for this annual award. Bob recognized the efforts of the Kennedy Award Committee in thanking Robin Andrews, Terry Schwaner, Lynnette Sievert, and Sam Sweet for their diligence and service.

Marion Preest announced winning selections in the Seibert Award competition for the 2001 meeting: Emily Moriarty (University of Texas-Austin), Travis LaDuc (University of Texas-Austin), Daniel Warner (Virginia Polytechnic Institute and State University), and John Marshall (Indiana-Purdue University-Fort Wayne) were chosen as the best student presenters in four categories (see below for details on Seibert Award winners).

Several students received support to the SSAR 2001 Meeting through Sherman Minton Student Travel Awards (David Hardy, Chair). These awards provided $200 to each winner and included the following individuals: Omar Attum (University of Louisville), Philip J. Bergmann (University of Calgary), Angelo Bufalino (Saint Louis University), Amanda Crnkovic (Louisiana State University—Shreveport), Caren S. Goldberg (University of Arizona), Sarah M. Holt (University of Guelph), Ulrich Kuch (University of Frankfurt), Richard M. Lehtinen (University of Michigan), Owen M. Lockhart (Indiana University of Pennsylvania), Michael N. Marchand (University of New Hampshire), Jason R. Rohr (Binghamton University), Michael J. Rubbo (Pennsylvania State University), Stacy N. Smith (University of Georgia), Rebecca Symula (East Carolina University), Ricardo Torres-Cervantes (Universidad Nacional Autónoma de México), Mark E. Walvoord (University of Oklahoma), and Christopher R. Wilson (Appalachian State University).

Henry Mushinsky presented information on future meeting events. The SSAR Board accepted meeting invitations for the next several years. These meetings will be joint events with the American Society of Ichthyologists and Herpetologists (ASIH) and The Herpetologists' League (HL). ASIH President Al Savitzky provided details for future dates and venues: 2002 – Kansas City, Missouri (3–8 July) to be held at the Westin Crown Centre Hotel; 2003 – Manaus, Brazil (in early June), planned for the Hotel Tropical Manaus along the banks of the Rio Negro; 2004 – Norman, Oklahoma (27 May–2 June); and 2005 – Tampa, Florida (date not set). At the Board meeting, Savitzky showed slides of the facilities in Kansas City and Manaus, and promised a good venue for both destinations. Accommodation packages are being arranged for the Brazil meeting and should represent a good opportunity for international travel. President Green announced that undistrib-

uted funds from SSAR student travel awards for 2001 would go towards offsetting travel costs to the 2003 meeting destination for those student members who apply for support.

Akira Mori summarized the activities of the Task Force for Non-US Members. Together with Karen Lips and Carlos Navas, Mori addressed several areas that the Task Force feels would better serve non-US members in the Society and help make SSAR a more internationally inviting organization. He summarized the ways in which SSAR may increase its international appeal with the following suggestions: 1) include more non-US reviewers and editors for Society publications; 2) create guidelines for editors of manuscripts submitted from non-English speaking authors that would result in positive comments; 3) expand the international scope of topical coverage in *Herp Review*; 4) hold the annual meeting at locations outside the United States; 5) create mirror, alternative-language websites for the Society homepage; 6) reduce the dues rate to non-US members to make it more financially attainable; and 7) advertise (in *Herp Review*) the willingness to embrace non-US member opinions. Speaking on behalf of SSAR editors, Bob Hansen stated that publication editors and reviewers already address grammatical and vocabulary concerns in a constructive fashion during the review process when dealing with manuscripts submitted from authors where English is a second language. Kraig Adler said US members should take an active role in reaching out to the international herpetological community. He encouraged US members to subsidize or sponsor non-US membership in SSAR. President Green asked all members working internationally to try and promote SSAR and increase international involvement of the Society.

George Pisani, SSAR Webmaster, reported that the SSAR website (http://www.ukans.edu/~ssar/SSAR.html) continues to see a lot of "hits" in terms of web visitation. Attempts to bring alternate language versions of the website are complicated and cumbersome, but progressing slowly—a Portuguese version is in the offing. President Green and members of the Board feel that the webpage should be enhanced to increase the delivery of the Society's mission and information. There was much discussion about online publication issues and how this may be linked to an expanded website for the Society. These and other approaches are being explored. President Green stated that a strong webpage would help to increase international involvement through computer access to the Society.

In other business, Al Savitzky motioned from the floor that SSAR should join the AIBS. After a brief debate by the membership, the motion was approved by a majority of those present.

—Respectfully submitted by John M. Matter, SSAR Secretary

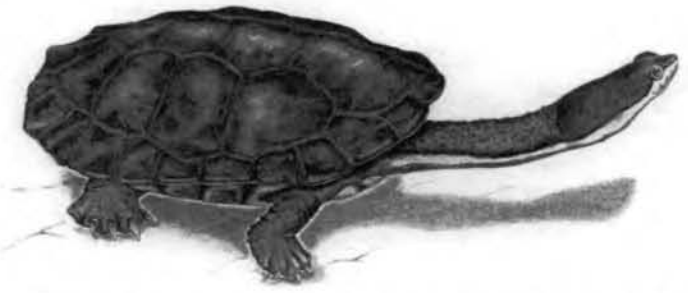
2001 Resolutions

Smithsonian Institution

WHEREAS, the National Museum of Natural History, Smithsonian Institution, has played a long and important role in the activities associated with the academic and professional scientific community, and

WHEREAS, the collections of the National Museum of Natural History are the largest in the world, document national and international biodiversity, are studied by hundreds of museum and university scientists every year, both professional and student, either through loans of material or personal visits, are critical to research on systematics and biodiversity studies worldwide, and are crucial to the advancement of science, and

WHEREAS, the excellence and diversity of the staff of the National Museum of Natural History, their many significant contributions to the increase and diffusion of knowledge, their critical role in basic research, and their support of scientific research worldwide, that contribute to the advancement of scientific knowledge; therefore,



BE IT RESOLVED that The Herpetologists' League, at their 49th Annual Meeting, and the Society for the Study of Amphibians and Reptiles, at their 44th Annual Meeting, in Indianapolis, Indiana 27–31 July 2001, urge the Regents of the Smithsonian Institution to review carefully any plans to restructure science at the Smithsonian's National Museum of Natural History, to ensure that the collections continue to be maintained at world-class standards and are made available for study by the international scientific community, and to ensure that the Museum's pivotal role in research in systematics, biogeography, comparative morphology, ecology, and conservation biology in the natural sciences is maintained and supported well into the future.

Adopted by the Society for the Study of Amphibians and Reptiles at its Annual Business Meeting, 30 July 2001.

Minton Travelling Fellowship Fund Donors

The following individuals, organizations, and institutions contributed to the Sherman A. Minton Travelling Fellowship Fund:

Kraig Adler, Robert Aldridge, Steven Anderson, Bern and Bette Bechtel, Charles Carpenter, Chicago Herpetological Society, Hal Cogger and Tim Cogger, Roger Conant, Carl Gans, J. Whitfield Gibbons, Itzchak Gilboa, Harry Greene, David and Billie Hardy, Hoosier Herpetological Society, John and Sheila Iverson, Daryl Karns and Pam Middleton, Kentucky Reptile Zoo, Bruce Kingsbury, Krieger Publishing Company, Michael Lodato, Madge R. Minton, Paul Moler, Robert Norris, Steve Perrill, Chris Phillips, Alan Resetar, David Sever, Hobart Smith, Margaret Stewart, and Richard Zweifel.

NEWSNOTES

Congdon Wins International Award

Justin Congdon, a senior research ecologist with the Savannah River Ecology Laboratory in Aiken, South Carolina (USA), has been awarded the 2000 Longevity Prize by the Fondation IPSEN, a French organization that supports work in the field of longevity. Since 1997 the annual prize has gone to researchers in such fields as biology, genetics, gerontology, demography, and statistics. Congdon is the first ecologist to win the award. Congdon received 100,000 French francs and delivered a lecture based on his work with longevity in Blanding's turtles in July 2001 at the World Congress of Gerontology in Vancouver, Canada.

"It is an honor, and quite a surprise, to be recognized by the Foundation IPSEN and scientists studying aging," said Congdon. "It is not often that a biologist working on a field study of life history evolution gets this kind of recognition, or any kind or recognition for that matter."

Congdon's research on the life histories of turtles is well known to the herpetological community. Over the past 26 years he has followed the lives of about 12,000 *Emydoidea blandingii* at the University of Michigan's E. S. George Reserve. The first 1,000 turtles were marked there between 1953–1957, so he has been able to follow the lives of both young and old individuals. He said, "I think that the demonstration that 60–70-year-old Blanding's turtles have traits that support hypotheses based on evolutionary theory better than those predicted by the senescence theory is what caught the eye of the scientists at the foundation."

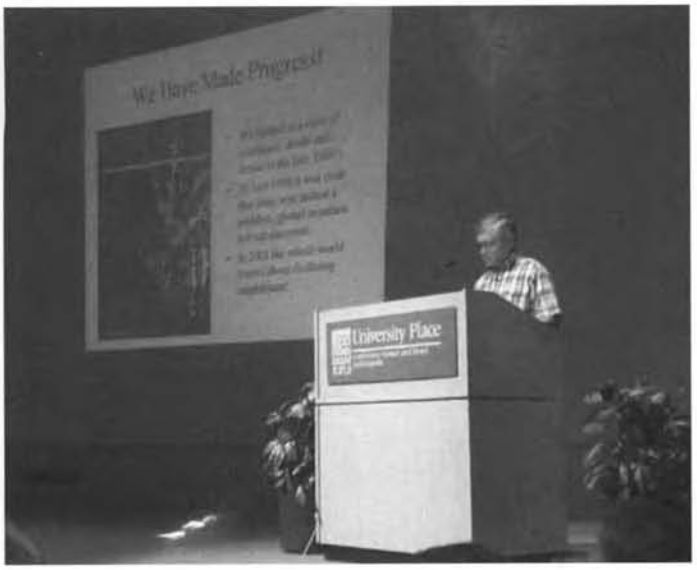
SSAR congratulates Congdon for this notable accomplishment.

Savannah River Ecology Laboratory scientist Dr. Justin Congdon (right) receives the 2000 Longevity Prize, given by the Fondation IPSEN, a French organization that supports work in the field of longevity. Shown with him is Yves Christen of IPSEN Foundation. Congdon is the first ecologist to win the award. Congdon is shown at the World Congress of Gerontology in Vancouver where he received 100,000 French francs and delivered a lecture based on his work with longevity in Blanding's turtles.

Ohio Department of Natural Resources Honors Conant

The Ohio Department of Natural Resources recently awarded its highest honor to Roger Conant, by inducting him into the ODNR Natural Resources Hall of Fame. Conant spent nine years studying Ohio's herpetofauna during the Great Depression for his book, *The Reptiles of Ohio*, still an essential regional reference. Through his research, writing, and legendary correspondence, he has influenced several generations of herpetolgists.

A sample of previous Hall of Fame honorees include the legendary Johnny Appleseed, physician-naturalist Jared P. Kirtland, Ohio-born explorer John Wesley Powell, botanist Lucy Braun, and conservationist/novelist Louis Bromfield.



Graduate and Post-Graduate Research Grants

The Biological Research Station of the Edmund Niles Huyck Preserve (www.huyckpreserve.org) offers grants (max. = $2500) to support biological research which utilizes the resources of the Preserve. Among the research areas supported are basic and applied ecology, animal behavior, systematics, evolution, and conservation. The 2000-acre Preserve is located on the Helderberg Plateau, 30 miles southwest of Albany, New York. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100-acre lakes, and several waterfalls. Facilities include a wet and dry lab, library, and houses/cabins for researchers. Deadline = 1 February 2002. Application material: *Dr. Richard L. Wyman, Executive Director, E.N. Huyck Preserve and Biological Research Station, P.O. Box 189, Rensselaerville, New York 12147, USA.*

Declining Amphibian Populations Task Force

The Declining Amphibian Populations Task Force (DAPTF) has continued its well recognized role in promoting and coordinating international scientific efforts to assess the scope of amphibian declines worldwide and to identify the causes for this decline. DAPTF Seed Grants during 2000–2001 distributed over US $40,000 to researchers. The number of regional and issue-based working groups continued to grow, and now stands at more than 100. At this last summer's SSAR/HL annual meeting in Indianapolis, Karen Lips (Southern Illinois University) and David Green (McGill University, Canada) organized on behalf of DAPTF a very successful two-day international symposium on amphibian declines. The symposium was extremely well attended and received considerable media attention. A similar symposium will take place at the Fourth World Congress of Herpetology in Sri Lanka in December.

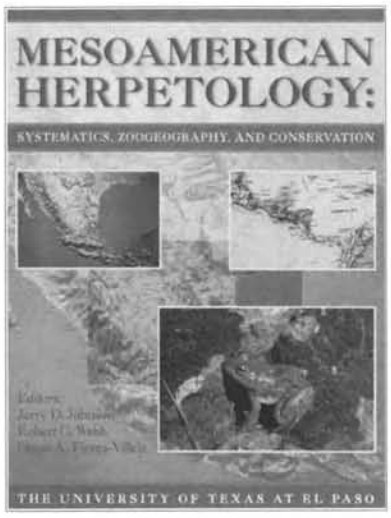
DAPTF efforts for 2002 will maintain all ongoing activities (e.g., *Froglog*, seed grants, working groups), as well as several new initiatives. The latter include DAPTF's participation and assistance with an ambitious Global Amphibian Assessment, which is being spearheaded by the Center for Applied Biodiversity Science at Conservation International.

At the Amphibian Population Declines Symposium in Indianapolis, David Wake reviewed the history of amphibian declines and summarized recent developments and new initiatives.

Pride in DAPTF's continued success is tempered by our growing understanding that the declining amphibian phenomenon is far more pervasive and severe than was appreciated only a few years ago. Yet, these facts only make the work of the Task Force more important. DAPTF's ability to assist scientific studies of declining amphibians and to work with governments and conservation organizations to devise sound strategies for saving natural populations is, to a considerable extent, a direct function of the amount of financial support received. Today, more than ever before, the Task Force depends critically on the donations received from private individuals. Persons or organizations wishing to make a donation to DAPTF should make checks payable to "Brookfield Zoo" and sent to: *DAPTF, Museum of Comparative Zoology, Department of Herpetology, 26 Oxford Street, Cambridge, Massachusetts 02138, USA.*

For U.S.-based donors, contributions to DAPTF are fully deductible for federal income tax purposes. Please contact the DAPTF headquarters (e-mail: Daptf@open.ac.uk) for information regarding payment in other currencies. Additional information about the Declining Amphibian Populations Task Force may be obtained from the DAPTF website: www.open.ac.uk/daptf/.

MEETINGS



Meetings Calendar

21–24 March 2002—The Desert Tortoise Council 27th Annual Meeting and Symposium, Palm Springs, California, USA. http://www.deserttortoise.org/.

5–7 April 2002—Current Research on Herpetofauna of the Sonoran Desert II, Tucson, Arizona, USA. http://tucsonherpsociety.org.

18–20 April 2002—3rd International Symposium on *Emys orbicularis*, Kosice, Slovak Republic. Hosted by Vychodoslovenske Muzeum Kosice in association with Museum fur Tierkunde Dresden and DGHT Rheinbach. Information: Peter Havas, e-mail: havasp@vakke.slposta.sk or www.cassovia.sk/emys.

3–8 July 2002—45th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists. Crown Center Hotel, Kansas City, Missouri, USA. Details will be available in the March 2002 issue of *HR* and will be posted on the SSAR web site: www.ukans.edu/~ssar.

New from the University of Texas at El Paso

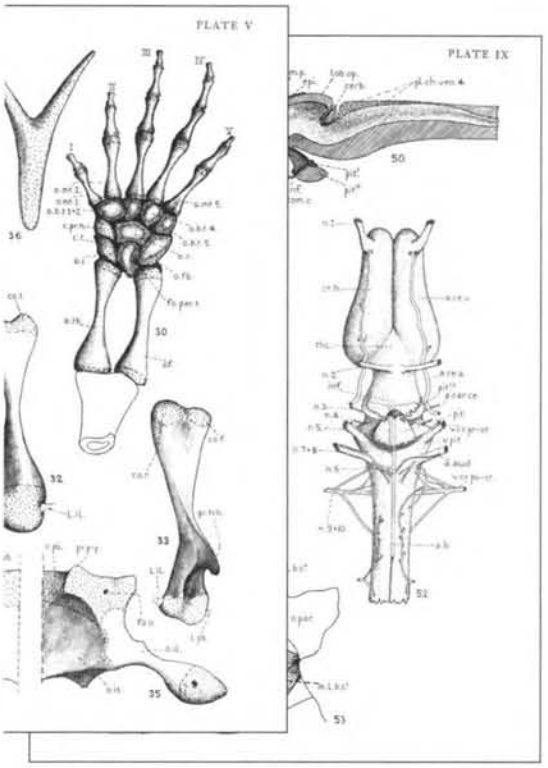
MESOAMERICAN HERPETOLOGY:
Systematics, Zoogeography, and Conservation

Jerry D. Johnson, Robert G. Webb, Oscar A. Flores-Villela
Editors

MESOAMERICA IS THE LANDMASS CONTAINING MÉXICO AND THE SEVEN COUNTRIES OF CENTRAL America. It has been the object of herpetological investigations for several centuries and continues to attract herpetologists from each of those countries and from foreign researchers as well. The high biotic diversity, including amphibians and reptiles, is well known, and is due to the large assortment of geological features and tropical environments found within the area. New information about various aspects of the herpetofauna continues to be produced and most certainly will be increased in the coming years.

Mesoamerican Herpetology: Systematics, Zoogeography, and Conservation is the result of a symposium, sponsored by the Texas Herpetological Society and the University of Texas at El Paso, which was dedicated to increasing our knowledge about the herpetofauna of Mesoamerica. Authors of all 12 included papers are acknowledged experts in the field.

200 pages, 8 x 11 inches, b&w illustrations, maps. US $28.00 + 4.00 shipping & handling
Texas residents must add 8.5% sales tax.



Two New Facsimile Reprints from the Society for the Study of Amphibians and Reptiles

THE ANATOMY OF THE SALAMANDER

by Eric T. B. Francis

Francis remains the starting place for virtually any rigorous study of salamander comparative or functional anatomy, and is an indispensible reference for studies of urodele developmental anatomy, endocrinology, and physiology.

—JAMES HANKEN, from the Foreword

FRANCIS'S *ANATOMY OF THE SALAMANDER*, PUBLISHED IN 1934, REMAINS one of the standard references in the herpetological and anatomical literature. It covers the anatomy of the European fire salamander, *Salamandra salamandra*, in 11 detailed chapters including external features, skeleton, muscles, nervous system, vascular system, urogenital system, ductless glands, and the skin and sense organs. The accounts are extremely thorough. For example, that on cranial nerve V (trigeminal) is six pages long; the branches of the systemic arch take another five pages; and each muscle is described in terms of its anatomy, invervation, synonymy, function, and homology. An added benefit is that Francis lists the relevant literature for each organ system; nearly 850 references are cited. He discusses homologies between structures in *Salamandra* and those in other salamanders and other vertebrates. He also covers the taxonomy, distribution, and life history of the salamanders of the genus *Salamandra*.

James Hanken, a leading vertebrate morphologist at Harvard University, provides an extensive foreword that puts Francis's book in historical context and reviews the relevant current literature. The book is illustrated with 25 highly detailed plates containing 84 fully labeled figures. There is an extensive index and a long historical introduction that reviews the classical literature on salamander biology beginning in the sixteenth century.

Specifications: 465 pages, 7 x 10 inches, 25 plates, colored frontispiece, clothbound. ISBN 0–916984–50–8. To be published February 2002.

REPTILE FAUNA OF CEYLON

by William Ferguson

THIS BOOKLET, ORIGINALLY PUBLISHED IN 1877, REPRESENTS THE FIRST COMPREHENSIVE AND FULLY ANNOTATED LIST OF the herpetofauna of Sri Lanka. It includes 41 species of amphibians and 139 of reptiles. It also gives a list of the Sinhalese common names. Two new and still-recognized species are described in this booklet: a gecko and a colubrid snake. A biography of Ferguson, a British surveyor and amateur naturalist who worked in Sri Lanka during 1839–1887, is added together with a list of his herpetological publications. This reprint is issued to commemorate the Fourth World Congress of Herpetology, to be held in Colombo, Sri Lanka, in December 2001.

Specifications: 48 pages, 5.5 x 8.5 inches, cardboard cover. ISBN 0–916984–59–1. To be published December 2001.

PRICES AND SHIPPING COSTS:

• FRANCIS: Pre-publication to SSAR members US$50; Institutions, non-members $60 • *Shipping*: USA address, add $4; non-USA $6.
• FERGUSON: Pre-publication to SSAR members US$6; Institutions, non-members $8 • *Shipping*: USA address, add $3; non-USA $4.

SEND ORDERS TO: Breck Bartholomew, P.O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone and fax*: area code 801, 453–0489; *e-mail*: ssar@herplit.com). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may also be charged to MasterCard or VISA (please provide the account number and card expiration date). SSAR membership information and a complete list of all Society publications can be obtained on request to Mr. Bartholomew.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Systematics of West Indian Toads

The *Bufo peltocephalus* Group is composed of 11 species of toads that are restricted to the Greater Antilles. A monophyletic origin of the group has been questioned because of disparate morphology, behavior, and ecology of the different species. The authors examined three mitochondrial genes (12S, 16S, and cyt *b*) from 8 West Indian toads and 10 outgroup bufonids to address the monophyly, relationships, and biogeography of the *B. peltocephalus* Group. Sequence alignment was performed with the CLUSTAL option in Sequence Navigator (version 1.01) and corrected by eye. Phylogenetic analyses were conducted with neighbor-joining by MEGA (version 2.0b2), and with parsimony and maximum-likelihood by PAUP* (version 4.0b4). All trees supported the monophyly of the *B. peltocephalus* Group. The data suggest support for a Cuban clade, and the sister-group relationship of *B. guentheri* (Hispaniola) with *B. lemur* (Puerto Rico). A New World origin for the West Indian clade of toads also is suggested by the data. Data from this study and others suggest overwater dispersal of this group, and not a late Cretaceous vicariant event.

Aging in an Emydid Turtle

The Relative Reproductive Rate Hypothesis contends that older individuals of long-lived species should possess traits that enhance reproductive success. The Senescence Hypothesis suggests that older individuals will experience a decline in reproductive success. The authors studied Blanding's turtle (*Emydoidea blandingii*) to address these hypotheses, and examined whether age and body size contribute to indeterminate growth with associated longevity. Turtles were marked, weighed, measured, and recaptured for years as part of this long-term study. Data on reproduction, nesting, predation, and mortality were collected as well; statistical analyses included Spearman's Rank Correlation, Wilcoxon tests, and survivorship curves (PROC LIFETEST). Results indicated that the oldest group of turtles had larger clutch sizes, but larger egg size was not associated with any age group. Older females had a significantly higher reproductive frequency than younger females. Older female nests experienced the lowest frequency of predation, but these nests had a higher likelihood of failure attributable to developmental problems. Survivorship did not differ significantly between the sexes, but older individuals survived longer than younger age groups. A strong relationship between body size and age was not found—body size does not appear to be a mechanism for increased reproductive output in older females. Although the data support both hypotheses, the authors contend that the Relative Reproductive Rate Hypothesis is best supported by the results.

Effects of Agricultural Disturbance on Lizard Diversity

Numerous studies have documented detrimental effects of ecological disturbance on biodiversity. The authors studied the effects of agricultural disturbance on lizard diversity in the Dominican Republic. Twenty-four plots representing 6 habitats ranging in complexity from abandoned pasture to *mogote* top were established in a protected national park. These plots were compared with 9 plots of active, agriculturally-disturbed habitats on the periphery of the park. Glue traps were utilized to capture lizards within the study plots. Species richness was analyzed with rarefaction; richness and eveness were analyzed together with Hulbert's Probability of Interspecific Encounter and the log series index (μ). Species richness was higher inside the park compared to the sites on the periphery of the park; active agricultural habitats exhibited the lowest diversity. The *mogote* sites are identified as the most species-rich habitat.

Feeding Mechanisms of Gopher and King Snakes

The simple body forms of snakes limit their movements to various axial bends and twists. Recent studies have suggested kinematic similarity between undulations associated with swallowing and lateral locomotion—including the use of the same muscles in some cases. The author examined the activation patterns and kinematics of swallowing in the epaxial muscles of five gopher snakes (*Pituophis melanoleucus*) and one king snake (*Lampropeltis*

getula). For experimental trials, snakes were placed in open glass aquaria, offered live mice, and videotaped at 30 frames s^{-1}. Measurement TV and Fin software was used to digitize the vertebral midline of the snakes, and calculate bending angles, respectively. Electrodes were surgically implanted into the snakes for electromyographic (EMG) readings; EMG readings were amplified and recorded on FM tape. Plethysmography was used to measure the pressure exerted by snakes on their prey. A multiple regression analysis was used to examine the relationship between muscle activity and vertebral bending. Three distinct stages of swallowing (snout shifting, concertion bending, and ventral flexion) were observed in relation to intraoral transport, and one distinct stage (undulatory bending) was noted for esophageal transport. Peak pressures (0.93–4.8 kPa) were noted at the commencement of a bend after a short hiatus in movement. These results suggest the epaxial muscles are integral lateral flexors to movement that involve large-radius bending, including locomotion and swallowing.

The Hyolingual Apparatus of Chameleons

Since 1733, anatomists and functional morphologists have studied the tongue projection mechanism of chameleons. The authors examined the hyolingual apparatus of seven species of chameleons (*Brookesia armorata, B. supraciliaris, Chameleo calyptratus, C. fischeri, C. jacksonii, C. oustaleti, and C. pardalis*) in order to increase knowledge of the muscles involved in tongue projection. Selected specimens were cleared and stained or sectioned for histological examination. Specific muscles were separated from specimens and stained for examination with a dissecting microscope, polarized light microscope, or scanning electron microscope. A detailed description of the hyoid apparatus, origin and insertion of hyolingual muscles, distribution of motor endplates, and histochemical properties of selected muscles is discussed. A thick connective tissue sheet between the tongue and hyoid apparatus was identified as a potential source of elastic strain energy—this structure may be responsible for tongue recoil. The results of this study suggest that the hyolingual apparatus is more complex than previously assumed in other functional morphology studies of chameleons.

Herrel, A., J. J. Meyers, K. C. Nishikawa, and F. De Vree. 2001. Morphology and histochemistry of the hyolingual apparatus in chameleons. Journal of Morphology 249:154–170.

Antipredatory Adaptations of *Chamaeleo chamaeleon*

Many species of animals with reduced locomotory abilities use camouflage as the main tactic to avoid predatory attacks. The authors studied the effects of camouflage on escape decisions in the common chameleon, *Chamaeleo chamaeleon* by performing experiments with humans as would-be predators. Effects of background vegetation and individual size of chameleons on the ability of a predator to detect the chameleons were analyzed both in the field and by examination of photographs. Probability of detection was significantly influenced by background and size of chameleons. Based on these results, the authors then analyzed how risk perceived by an individual chameleon influenced its escape decisions. They found that the type of defensive display was different for individuals of different sizes and in different conditions. The results of this study indicate that camouflage has a significant effect on individual escape decisions and that some antipredatory responses are size-dependent.

Systematics of Skinks in the Genus *Eumeces*

The scincid genus *Eumeces* is composed of over 50 morphologically and ecologically variable species occurring throughout most of the Holarctic region of the world. The authors conducted a phylogenetic analysis of the genus *Eumeces*, and included the genera *Scincopus* and *Scincus* in their ingroup. Because of the lack of knowledge regarding basal scincid phylogenetic relationships, the authors included nine genera of the family Cordylidae in the outgroup. However, general comparisons were made between the ingroup and other scincid taxa. The phylogenetic analysis was conducted with 16 morphological characters (14 unambiguously polarized), and heuristically analyzed using PAUP* version 4.0b1. One fully resolved, most parsimonious tree (19 steps) was obtained from the analysis. The analysis indicated: 1) the *Pariocela* species group (39 species) is monophyletic; 2) the *schneiderii* (5 species), *schwartzei* (3 species), and *taeniolatus* (2 species) species groups are more closely related to each other and the *Scincopus* and *Scincus* genera than they are to the *Pariocela* species group; 3) *Scincopus*, *Scincus* and the *schneiderii* and *taeniolatus* species groups form a monophyletic group; 4) the *schneiderii* species group shows several synapomorphies with *Scincopus* and *Scincus*; and 5) *Scincopus* and *Scincus* share a common ancestor. The authors propose a new subfamily (Eumecinae) solely for the genus *Eumeces* (39 species), recognition of the genus *Eurylepis* for the *taeniolatus* species group, the new genus *Mesoscincus* for the *schwartzei* species group, and the new genus *Novoeumeces* for the *schneiderii* species group.

Genetic Divergence of Chinese Giant Salamanders

The Chinese giant salamander (*Andrias davidianus*) is the largest species of amphibian in the world, and it is restricted to mainland China in the Yellow, Yangtze, and Pearl rivers. This species is currently listed under CITES Appendix I because of habitat destruction and human consumption. The authors utilized isozyme electrophoresis (40 loci) and two mt DNA genes (ATPase 6 and cyt *b*) to assess the genetic diversity of 6 populations of salamanders, and to test the null hypothesis that all the populations represent a single species. Results from allozyme data indicated a deficiency in individual heterozygosity, and that *A. davidianus* is not a panmictic species. Genetic divergence levels did not indicate recognition of more than one species, although one population from Huangshan possessed three unique, non-homoplastic synapomorphies (mtDNA) and unique alleles at two loci (isozymes). Lack of geographic correlation is a likely consequence of human relocation of salamanders. The authors suggest a conservation strategy that preserves the maximum amount of genetic diversity.

R. W. Murphy, J. Fu, D. E. Upton, T. de Lemas, and E. Zhao. 2000. Genetic variability among endangered Chinese giant salamanders, *Andrias davidianus*. Molecular Ecology 9:1539–1547.

Phylogenetic Relationships of Lissamphibia

The morphological diversity and poor fossil record of living amphibians has complicated efforts to reconstruct the phylogenetic relationships of these animals. Although most modern studies have accepted the monophyly of Lissamphibia (salamanders, caecilians, and frogs), the identification of the sister group and ingroup relationships remains contentious. To address the issue of amphibian monophyly, the authors sequenced the entire mitochondrial genomes of a salamander (*Mertensiella luschani*) and a caecilian (*Typhlonectes natans*); these sequences were compared to the mt genome of the frog *Xenopus laevis* and 9 other tetrapod taxa. Nucleotide sequences were aligned with CLUSTAL X and refined by eye. Maximum parsimony with heuristic searches, neighbor-joining, and maximum likelihood analyses were performed with PAUP* version 4.0b4a. All three analyses produced the same tree topology, which confirmed the monophyly of Lissamphibia and placed salamanders and frogs in a sister group relationship; this study supports the Batrachia (Caudata+Anura) hypothesis. These results can be utilized in future studies to: 1) examine phylogenetic relationships within salamanders and frogs; 2) compare vertebral development in salamanders and caecilians; and 3) compare brain development and limb morphology in Lissamphibia.

Tail Loss and Vulnerability of the Skink *Lampropholis guichenoti* to Predation

Tail loss is an effective defense mechanism used by many species of lizards to evade predators. However, tail autotomy may reduce an individual's subsequent fitness and ability to avoid predators. The authors examined how predatory interactions between the common garden skink *Lampropholis guichenoti* and two snake predators are influenced by behavioral shifts induced by tail autotomy of the prey. A series of experiments were performed to estimate nonrandom consumption vs. active selection of tailed and tailless skinks by the diurnal snake *Demansia psammophis* and the nocturnal snake *Rhinoplocephalus nigrescens*. In addition, the differential vulnerability to predation of tailed and tailless lizards was analyzed. The experiments with the diurnal predator resulted in tailless skinks being more susceptible to predation than tailed skinks. In contrast, experiments with the nocturnal predator indicated that skink vulnerability was not affected by tail autotomy. Reduced escape speed of tailless skinks may have increased vulnerability to predation by the diurnal snake, whereas selection of overnight shelters by skinks affected the probability of predation by the nocturnal snake. This study demonstrates that snake-lizard systems are good predator-prey models that can be used in ecological studies.

Downes, S., and R. Shine. 2001. Why does tail loss increase a lizard's later vulnerability to snake predators? Ecology 82(5):1293–1303.

Use of Cover Objects for Sampling Snakes

One of the most effective sampling methods for amphibians and reptiles is the use of artificial cover objects. This method minimizes disturbance of microhabitats and is very useful in ecological studies. The authors tested the effectiveness of three kinds of covers by sampling the secretive snake *Contia tenuis* and three species of *Thamnophis*. Black asphalt, corrugated tin, and plywood were used to build more than 50 cover-stations in the Gulf Islands, British Columbia. Differences in the use of the three cover types were analyzed using contingency tables and the Chi-square test. The snakes used plywood covers less frequently than asphalt and tin covers—probably because the latter two materials heat up rapidly in the sun and become a good source of heat. Artificial cover objects were found to be useful in studying secretive snakes. However, this sampling method might contain biases, such as the sampled individuals not being representative of the population. Thus, potential biases of this method need to be examined in population studies.

ENGELSTOFT, C., AND K. E. OVASKA. 2000. Artificial cover-objects as a method for sampling snakes (*Contia tenuis* and *Thamnophis* spp.) in British Columbia. Northwestern Naturalist 81:35–43.

Lizard Abundance in Guana

Despite the importance of accurate population density estimates in ecology, many studies of lizard abundance are biased because selection of study sites is commonly based on the high density of the species studied. The authors quantified absolute population densities of lizards with four 10 x 10 m forest removal plots in Guana Island, British Virgin Islands. Early successional and mid-successional forests were surveyed, and the results were compared with data of a previous study made in the island of Guam, Mariana Islands. Of the 1401 lizards obtained, 94.5% corresponded to the diurnal gecko *Sphaerodactylus macrolepis*, which was found primarily in leaf litter. With a density of 67,600 ha^{-1}, *S. macrolepis* was found to be the densest terrestrial species among non-aggregated vertebrates. Therefore, this lizard represents an excellent model organism for ecological studies in spite of its secretive habits and small size. Lizard assemblages in Guana are similar to those in Guam only in that litter insectivores are the densest species. The main difference between Guam and Guana is that Guana lacks nocturnal species, whereas in Guam nearly half of all terrestrial vertebrate individuals correspond to nocturnal species. This dissimilarity between guild abundances in Guana and Guam contrasts with the significant overlap in assemblage structure between both islands. The authors concluded that some process other than community adaptation significantly influences ecological roles and potential abundances.

Dipteran Parasites of Loggerhead and Green Sea Turtle Nests

Larvae of the dipteran families Phoridae and Sarcophagidae have been found in marine turtle nests in many parts of the world. The authors studied dipteran infestation of loggerhead *Caretta caretta* and green sea turtle *Chelonia mydas* nests in northern Cyprus. Dipteran larvae were found and collected during nest excavation in 1996 and 1997, and were identified by keeping some larvae in jars until adult flies emerged. Eleven species of Diptera were found in nests of both turtle species; however, loggerhead nests had more diversity and abundance of dipteran parasites than green turtle nests. By examining developmental periods of three dipteran species, the authors found that larvae developed in loggerhead nests faster than in green turtle nests. The levels of infestation found in northern Cyprus are lower than those of other species of marine turtles reported from other areas in the world. Although dipteran infestation seems to have no effect on the hatching success of nests, the authors recommend further study given the endangered status of sea turtles in the Mediterranean.

MCGOWAN, A., A. C. BRODERICK, J. DEEMING, B. J. GODLEY, AND E. G. HANCOCK. 2001. Dipteran infestation of loggerhead (*Caretta caretta*) and green (*Chelonia mydas*) sea turtle nests in northern Cyprus. Journal of Natural History 35:573–581.

Chemical Alarm Cues of the Ravine Salamander *Plethodon richmondi*

Many animals reduce the probability of encountering a predator by adopting avoidance behaviors after detecting the predator through chemical alarm cues. These substances are released upon physical injury by members of the same species or prey guild to communicate the presence of danger. The authors examined the ability of the ravine salamander *Plethodon richmondi* to detect and respond to chemical alarm cues from autotomized tails of conspecifics and of zigzag salamanders (*P. dorsalis*). All individuals were collected in Madison County, Kentucky, and six substrate-choice tests were conducted on consecutive nights. Ravine salamanders detected and avoided chemical cues released from autotomized tails of conspecifics and this response was independent of size and sex. Alarm cues released by zigzag salamanders were not avoided. Thus, ravine salamanders increase their chances of survival by avoiding areas where a conspecific has been injured.

HUCKO, J. A., AND P. V. CUPP. 2001. Avoidance of chemical alarm cues released from autotomized tails of ravine salamanders (*Plethodon richmondi*). Ethology 107:315–322.

Assessment of sex is essential to many ecological studies. Among amphibians, sexually dimorphic traits include size, vocalizations, and coloration. Males of many frog species develop pigmented vocal sacs during the breeding season (Duellman and Trueb 1986). In calling males of several hylids (e.g., *Pseudacris crucifer*: W. Duellman, pers. comm.) and the bullfrog *Rana catesbeiana* (Howard 1981), the throats become bright yellow. In the cave frog *Eleutherodactylus cooki*, males with the greatest reproductive success have throats with yellower color than their average ventral coloration (Burrowes 2000). Although yellow throat coloring is unknown in urodeles (but mental glands are sometimes distinguishable in plethodontid salamanders; Houck and Sever 1994), I found white (September–October) and yellow (April–May) pigmented patches in the throat region of adult males of the migratory salamander *Salamandrella keyserlingii* (Hynobiidae). Here I propose how to distinguish sex of this species visually during the terrestrial phase, focusing on seasonal fluctuations of both throat coloration in adult males and development of "ovisacs" (sensu Hasumi 1996b) in adult females. I further present a description of increased head width, tail height, and body mass in aquatic-phase males, similar to those of *Hynobius nigrescens* (Hasumi and Iwasawa 1990).

I studied *S. keyserlingii* inhabiting a wetland in Otanoshike, Kushiro-shi, Hokkaido Prefecture, Japan (43°01'02"N, 144°17'38"E; 4 m elevation). I captured 40 aquatic adults by netting from a fen (oviposition site: Hasumi and Kanda 1998) during the April–May breeding season (1995, examined for 15 days), and 633 terrestrial individuals near the fen during the April–May breeding season (1996–1997, 56 days) and the June–October nonbreeding season (1995–1997, 141 days), using a large grid of 160 pitfall traps within a 100 x 55 m area, composed of forest and marsh. I recorded sex, sexual maturity, age class (i.e., juvenile or adult), and visual characteristics of each individual (see below). I weighed each individual for body mass (M) with a portable beam balance (to within 0.05 g), and measured snout–vent length (SVL, distance from the tip of the snout to the posterior angle of the vent), broadest head width (HW), and maximum tail height (TH) with digital calipers (to within 0.01 mm) by a modification of Wise and Buchanan's (1992) method without using anesthesia. I marked 30 aquatic adults and 516 terrestrial individuals by toe-clipping, and released them either to the fen or near the pitfalls where they were trapped. Subsequently, 105 animals (70 adult males, 30 adult females, 1 unsexed individual, and 4 juveniles) were recaptured in pitfall traps. In one instance, I found only an adult-size tail (from base to tip) in a pitfall trap; it was classified as an unsexed individual. I compared mean SVL between adult males having brilliant and pale yellow throats during the April–May terrestrial phase, and mean HW, TH, and M between terrestrial- and aquatic-phase males, using the Aspin-Welch test when exhibiting unequal variances (Snedecor and Cochran 1980) or Student's t-test ($\alpha = 0.05$, two-tailed).

A tubercle at the anterior angle of the vent (Hasumi et al. 1990; Sato 1943) was never discernible in either sex throughout the year, even during the aquatic phase, and therefore was a poor predictor for distinguishing adult males from others. In contrast, the throat region was a reliable predictor of sex. In adult males, this region assumed a translucent, grayish color from June–August (Table 1). It was translucent white during September and changed into an opaque, white patch during October. This patch turned a brilliant or pale yellow during the terrestrial phase of the April–May breeding season or during breeding immigration. However, some variation in male throat color occurred during this period; when 3 adult males which had a brilliant yellow throat were recaptured during April–May, their throats showed a pale yellow color (dates of capture and recapture, 28 April 1996 and 6 May 1996, 28 April 1996 and 10 May 1996, 30 April 1996 and 22 April 1997). A male's whole body, including this yellow coloring of the throat, became somewhat dusky during the aquatic phase. In terrestrial individuals other than adult males, the throat region took on a translucent, grayish color with or without a pinkish tinge throughout the year.

All size measures differed between males of different phases of the life cycle. First, males with brilliant yellow throats were larger than pale yellow males (SVL; brilliant: N = 110, mean = 56.65 mm, SD = 4.72, range = 46.21–66.75; pale: N = 18, mean = 53.46 mm, SD = 4.63, range = 47.18–62.14; t = 2.668, df = 126, $P = 0.009$). Head width of terrestrial-phase males, including breeding immigrants (HW: N = 317, mean = 9.23 mm, SD = 0.64, range = 7.46–11.01), was smaller than that of aquatic-phase males (N = 39, mean = 11.34 mm, SD = 0.85, range = 9.73–13.76; t = 15.015, df = 43, $P < 0.001$). Similarly, a tailfin never developed in terrestrial-phase males, including breeding immigrants (TH: N = 317, mean = 7.13 mm, SD = 0.72, range = 5.47–9.24), but was enlarged in aquatic-phase males (N = 39, mean = 9.41 mm, SD = 0.90, range = 7.49–11.95; t = 15.153, df = 44, $P < 0.001$). Around the end of each breeding season (mid-May), the tail assumed a fin-like appearance in 9 emigrating males. In early June, after breeding activity ceased, a slightly developed tailfin was found in 6 trapped salamanders (classified as adult males because of an undeveloped tailfin in females). Lastly, adult male body mass differed between the terrestrial phase (M: N = 317, mean = 4.58 g, SD = 1.06, range = 2.50–8.20) and the aquatic phase (N = 39, mean = 5.60 g, SD = 0.91, range = 2.50–8.35; t = 5.745, df = 354, $P < 0.001$).

Ovisac development was a reliable predictor of gravid females. A pair of beige ovisacs were visible through the skin of the ventral side of the torso near the hindlimbs (without holding females up to a light) during September, October, and the April–May breeding season (118 females examined). In general, the ventral region tended to assume a pinkish color in adult females and a dark brown color in adult males throughout the year with the exception of both sexes having an intermediate venter color with or without

many white dots. I verified this propensity during September–May, and applied it to distinguishing sex during June–August.

I identified sex and sexual maturity visually in 476 terrestrial adults (317 males, SVL mean = 57.51 mm, SD = 4.57, range = 46.21–69.49; 159 females, SVL mean = 61.99 mm, SD = 4.75, range = 52.00–72.33) by examining secondary sexual characteristics such as throat coloration, ovisac development, tailfin remaining (during September–May and early June), and venter color (during June–August). However, 5 terrestrial individuals captured from September–May and 19 terrestrial individuals captured from June–August did not show any clear sexually dimorphic trait, and therefore were classified as unsexed individuals (SVL: N = 24, mean = 55.50 mm, SD = 3.76, range = 52.24–66.67). I used SVL to distinguish unsexed individuals (SVL ≥ 52.00 mm) from juveniles (SVL < 52.00 mm) by applying the adult female's minimum SVL (52.00 mm; for comparison, the adult male's minimum SVL = 46.21 mm). Additionally, 67 juveniles (SVL: N = 67, mean = 46.60 mm, SD = 3.66, range = 37.43–51.85) and 65 metamorphs (N = 63, mean = 31.18 mm, SD = 3.05, range = 23.11–39.77; measures were not obtained from 2 metamorphs) were captured in pitfall traps.

TABLE 1. Seasonal color changes in the throat region in 317 adult males of *Salamandrella keyserlingii* during the terrestrial phase of the April–May breeding season (1996–1997, examined for 56 days) and the June–October nonbreeding season (1995–1997, 141 days).

Time of year	Translucent gray	Translucent white	Opaque white	Pale yellow	Brilliant yellow
April	0	0	0	5	99
May	0	1	1	13	11
June	19	1	0	0	0
July	11	0	0	0	0
August	15	0	0	0	0
September	0	99	16	0	0
October	0	0	23	3	0

Little literature exists on seasonal changes in throat coloration in urodeles. My observations on *S. keyserlingii* may be the first to report seasonal color changes in the throat region of urodeles from translucent gray, through opaque white, to brilliant yellow. It is unknown whether the absence of a prior description of this type in *S. keyserlingii* (Borkin 1999; Kuzmin 1999) reflects geographic variation in throat color. The intense yellow coloring of the throat is a striking secondary sexual characteristic in mature males, and may play an important role in sexual selection. Male throat color may be a signal for mate attraction and stimulation (Emlen and Oring 1977; Verrell 1991) or it may be involved in aggressive signalling between breeding males (Halliday and Tejedo 1995), which defend spawn sites on dead leaves of sedges.

In lentic-breeding hynobiids, a tubercle at the anterior angle of the vent is generally seen in breeding males (Sato 1943). Such a tubercle is evident in adult male *H. nigrescens* throughout the year except from May–July when ventral glands are underdeveloped (Hasumi et al. 1990), but is always lacking in adult females (Hasumi 1996a). This structure is a target for androgen (Hasumi et al. 1993), and may control ejaculate expenditure or fertilization duration during scramble competition among males for mates (Hasumi 2001). In contrast, although *S. keyserlingii* appears to have morphological characteristics of lentic-breeding hynobiids (Sato 1943), males lack this tubercle. It is unknown whether this exception reflects differences between genera.

An increased head width is unknown in urodeles other than hynobiids. The male head, body, and tail become swollen and inflated with water during the aquatic phase in *H. nigrescens* (Hasumi and Iwasawa 1990). This was evident in *S. keyserlingii*. Mating ball duration (i.e., fertilization duration) is shorter when males with increased head widths monopolize egg sacs during scramble competition in *H. nigrescens* (Hasumi 1994). Although there is no evidence for this in *S. keyserlingii*, which also forms a mating ball, it is likely that an increased head width in these species is involved in male–male competition for mates.

Acknowledgments.—Cordial thanks are due to Fusayuki Kanda and all staff members of Onnenai Visitor Center, Kushiro Shitsugen National Park, for their partial support during my stay in Kushiro. I have benefited from useful pieces of information about throat coloration from William Duellman. I am greatly indebted to Tim Halliday, Lynne Houck, Jeff Parmelee, and David Sever for critically reviewing a draft of the manuscript. I wish to express my gratitude for the constructive comments of Dede Olson, Paul Verrell, and Kurt Grossenbacher. Handling of *S. keyserlingii* is regulated by the Government of Kushiro-shi, and this study was conducted under the permission authorized by this Government. This study was financially supported in part by Grants-in-Aid for Scientific Research from the Japanese Foundation for the Management of Riparian Environments, the Maeda Ippo-en Foundation (Japan), and the Akiyama Memorial Foundation (Japan) for the Promotion of Life Sciences.

Color Pattern, Predator Avoidance, and Foraging Behavior in the Golden Frog *Colostethus beebei* (Anura: Dendrobatidae)

GODFREY R. BOURNE
Department of Biology, University of Missouri-St. Louis
St. Louis, Missouri 63121-4499, USA
e-mail: bourne@jinx.umsl.edu

Grafen (1991) indicated that animals are elusive prey, efficient foragers, or efficient predators, so they are maximizers of one sort or another. Thus, in this paper I focus on qualitative descriptions of color pattern, predator avoidance and foraging behavior in *Colostethus beebei*, a small, diurnal, presumably nontoxic member of the neotropical poison frog family Dendrobatidae. This species lives and breeds only on the giant terrestrial tank bromeliad, *Brocchinia micrantha*, in Guyana, South America (Bourne et al. 2001). Because *C. beebei* is a small, apparently nontoxic frog, it may be the target of many vertebrate and invertebrate predators. Thus, natural selection should favor the ability to avoid detection and minimize predation. The specific objectives of this observational study were to document: (1) color-pattern polymorphism (the simultaneous occurrence of two or more discrete, genetically-based phenotypes in a population, in which the frequency of the rarest type is higher than can be maintained by recurrent mutation; Ford 1975), crypsis, and fleeing and hiding behaviors of *C. beebei*; and (2) diet and methods of prey acquisition.

Materials and Methods.—I studied an individually marked population of 180 toe-clipped (Hero 1989) *C. beebei* on the tepui *Brocchinia* spp. glades of Kaieteur National Park, Guyana. The study was periodically conducted over 14 visits, of 1 to 7 days, from March 1993 to March 1999 (Bourne et al. 2001). My study site was the 455 m plateau near Kaieteur Falls (05°10'23"N; 59°28'52"W). I used focal animal sampling (Altmann 1974) of 30 randomly selected frogs to observe and record predator avoidance and foraging behaviors, and averaged 2.4 ± 0.6 h on each frog. Randomization was accomplished by placing the identification numbers of each frog in a paper bag and blindly choosing the frogs to be observed on a given day. Observations were initiated at 0530 h and ended at 1800 h, and were sometimes aided by binoculars. I spent over 281 h in these activities. Each of the 180 hand-captured *C. beebei* adults was assigned to one of five color-pattern types. Frogs were compared to color standards of Smithe (1975) between 1000 and 1200 h on cloudless days to subjectively differentiate among polymorphic types. I also used Smithe's (1975) color nomenclature to describe color variation among morphs.

Active antipredator behavior was evaluated primarily by observing and describing the responses of adult and larval *C. beebei* to human approaches and hand captures. Antipredator behavior was also elucidated through fortuitous observations of encounters between *C. beebei* and a colubrid snake, and three incidences of graspid crab attacks on an adult, tadpole, and nonaquatic eggs (Bourne et al. 2001). Death-feigning was observed in *C. beebei* after some frogs were persistently pursued during futile attempts to hide in more than two locations.

Leaf colors (green or brown) associated with the leaf-sitting *C. beebei* morphs (brilliantly colored or brownish) were evaluated by Chi-square tests of independence (Sokal and Rohlf 1995), along two 200-m transects on 16 June 1994 and 25 March 1999. The June transect was adjacent to the falls and was constantly bathed in the falls' mist, and the March transect was to the north of the landing strip and 805 m from the falls (Bourne et al. 2001).

To determine whether these conspicuous, yellow *C. beebei* sitting on green leaves reflected infrared light (700–900 nm; Schwalm et al. 1977), I used a qualitative method of assessment in October 1999. A captive *C. beebei* was photographed on a *Canna glauca* leaf with Kodak Infrared Ektachrome through a Y-2 yellow filter. Furthermore, in March 2000 a brown morph of *C. beebei* was photographed on both brown and green *B. micrantha* leaves. The Y-2 yellow filter excludes blue light, causing a shift in colors such that green objects appear blue, red objects appear green, and infrared reflectance appears red (Mason 1970; Schwalm et al. 1977).

In 1993, I noticed that the base color (the dominant color of the dorsum below the brown stippling) in captive *C. beebei* was fading. To determine whether their fruit fly (*Drosophila melanogaster*) diet supplied enough carotenes, I added 2% paprika to commercial fruit fly medium and subsequently evaluated color changes in the frogs. Six experimental frogs were maintained on fruit flies fed the paprika-enriched medium during their larval development, and six control frogs were fed flies reared on unfortified medium. Color acquisition by experimental frogs was evaluated visually, and control frogs were fed fruit flies maintained on 2% paprika

after 4 mo.

Results.—Colostethus beebei exhibited color-pattern polymorphism with base colors ranging from spectrum orange, orange yellow, buff-yellow, cream to spectrum yellow (color nomenclature; Smithe 1975). Some individuals were uniformly colored, but many had variable amounts of brown stippled on their dorsal surfaces, whereas others had oblique lateral stripes (*sensu* Edwards 1974) accented by ventral lines of dusky brown running from the posterior nares through the eye to the groin. Most individuals (80% of N = 180 frogs) had distinct oblique lateral stripes extending from the posterior margin of the eye toward the tip of the urostyle that did not dip down to groin (but see Noble 1923). The skin on the dorsum was smooth, somewhat granular on the sides, and smooth ventrally. Rings around the nares were either jet black or dusky brown, and horizontal pupils were set off by gold-colored irises with zero to two black flecks.

I recognized five discrete color patterns in the 180 *C. beebei* examined in this study, of which the first three morphs listed were brilliantly colored (Table 1): (1) spectrum yellow overall with suffuse dusky brown stippling on the dorsum. Bilateral but distinct cream colored oblique lateral stripes outlined ventrally by much narrower dusky brown lines running from the nares to the groin. Twenty-four percent or 43 frogs represented this morph; (2) this morph was similar to the proceeding morph, but the base color was spectrum orange to orange yellow, 19% or 35 frogs belong to this morph; (3) 20% or 36 frogs had a cream base color without distinct oblique lateral stripes; (4) buff-yellow base color, distinct oblique lateral stripes, and much dusky brown stippling dorsally just anterior to the vent, and distally on the dorsal surfaces of thighs and shanks (18% or 33 frogs); and (5) 18% or 33 frogs had a base color of spectrum yellow, with heavy even brown stippling on the entire dorsum and flanks, giving the appearance that these individuals were dusky brown. Frogs in this category also had distinct oblique lateral stripes. Although most morphs were conspicuously colored, a crude bioassay, a taste test for the presence of skin alkaloids (Daly et al. 1997), suggested that *C. beebei* was not toxic. However, infrared color photography indicated that this species reflected light in the near-infrared region (700–900 nm), as did the green and brown leaves on which these frogs sat.

Spectrum orange through spectrum yellow morphs with little or no brown stippling, and those with much brown stippling, were territorial on differently colored leaves of *B. micrantha*. Brilliantly colored individuals were more often seen on live, green leaves, while brown stippled frogs were recorded on the lower, dead, brown leaves of bromeliads (June 1994, $\chi^2 = 59.04$ with Yates correction, df = 1, $P < 0.0001$; March 1999, $\chi^2 = 8.34$ with Yates correction, df = 1, $P = 0.004$).

Active antipredator behavior included a high degree of wariness combined with rapid jumping into water at the base of bromeliad leaves. This was followed by complete submersion and wedging between the two leaves forming an axil. *Colostethus beebei* tadpoles also employed wedging behavior when approached by a potential predator. When persistently pursued by humans, 2% (N = 180 frogs) of adult *C. beebei* became limp, but with hind limbs stiffly extended (see Garcia 1999), and floated to the surface motionless. These individuals appeared to be dead. One death-feigning individual remained in this posture for at least 31 min. I fortuitously observed active predation of *C. beebei* on four occasions. The first predation episode consisted of a 1030 mm snout-vent length colubrid snake, *Imantodes cenchoa*, that pursued and caught a wedged adult *C. beebei* in a bromeliad pool. This snake swallowed the frog head-first in 38 sec. The other three predation episodes involved an unidentified species of graspid crab; each crab ate a live adult frog, a live stage 42 tadpole (*sensu* Gosner 1960), and a clutch of four foliar eggs, respectively.

Colostethus beebei was primarily a sit-and-wait predator, and foraging was closely linked to calling and sentinel behaviors on all-purpose territories (Bourne et al. 2001). Some food was captured after short distance hopping pursuit of crawling prey such as ants (Formicidae), mites (Acari), and small spiders (Araneae). However, most of the observed feeding events suggested that much of the diet consisted of intercepted emerging imagoes of mosquitoes (*Anopheles* sp., *Culex* sp., *Trichoprosopon* sp., *Wyeomiya* sp.), and midges (Chironomidae) as they left the surface of phytotelmata. Unidentified Drosophilidae flies attracted to nonaquatic clutches of *C. beebei* were also readily eaten.

Colostethus beebei apparently owed its brilliant base color to diet-derived carotenes. In captivity the brilliant spectral yellows and oranges faded in a few months. Six experimental frogs, fed fruit flies on a paprika-fortified diet, began regaining bright coloration after 2.5 wk. Six control frogs, maintained on a fruit fly diet without paprika, continued to lose color. Yet, these controls regained bright coloration when fed paprika-fortified fruit flies after 4 mo into the experiment.

Discussion.—I found five color-pattern morphs in *C. beebei*, a situation not unlike that for *C. taeniatus* in Ecuador (Edwards 1974), the unrelated *Eleutherodactylus coqui* in Puerto Rico (Pough et al. 1996), as well as 225 other frog species (Hoffman and Blouin 2000). What are the benefits of color polymorphism in prey organisms? Hoffman and Blouin (2000) indicated that the main explanation for the maintenance of color-pattern polymorphisms is direct selection by visually-oriented predators. One plausible hypothesis is that when a visual predator discovers a prey item it may form a search image for that particular color pattern and concentrate on seeking additional prey that look the same (Dawkins 1971; Pietrewicz and Kamil 1977, 1981). Thus, if all members of the population exhibit the same color pattern, then all individuals are at risk of easy detection. Alternatively, the presence of multiple color patterns decreases the chances of detection by a predator using a search image for a single morph. Pietrewicz and Kamil (1977, 1981) tested this hypothesis by randomly projecting a series of polymorphic prey slides to blue jays (*Cyanocitta cristata*). They corroborated the hypothesis because jays encountering polymorphic prey had difficulty forming an effective search image, and so could not easily switch to different prey morphs (Pietrewicz and Kamil 1977, 1981). Thus, polymorphism can reduce the risk of predation on individuals in mixed-morph populations (Pietrewicz and Kamil 1977, 1981), and may similarly benefit the color-based polymorphic *C. beebei*.

In addition to the apparent benefits of reduced predation accruing from color polymorphism, brightly colored *C. beebei* morphs were seen more often on live green leaves, and brown stippled morphs were encountered more often on dead brown leaves. Cryptic animals can minimize chances of detection by selecting appropriate backgrounds. To some extent, concealing coloration (Norris and Lowe 1964), especially of the brown morphs, may have pro-

tected them from high rates of predation, as suggested by experiments conducted by Tordoff (1980) and Morey (1990). Both of these laboratory experiments demonstrated that substrate matching significantly increased the survival of stationary frogs (Tordoff 1980; Morey 1990). It is more difficult to make this argument for the benefits of concealing coloration for yellow morphs of *C. beebei* on green leaves because they seemed conspicuous. However, it cannot be assumed that animals which do not appear cryptic to us are necessarily conspicuous to other animals. For example, snakes and birds, two groups that include frogs in their diets, can detect near-infrared radiation (Bradbury and Vehrencamp 1998). Yellow morphs of *C. beebei* are similar to other species of leaf-sitting *Centrolenella* and *Agalychnis* that reflect near-infrared light, and accrue protection because infrared reflectance from green leaves matches the frogs to the leaves (Schwalm et al. 1977). Even brown *C. beebei* morphs reflected near-infrared light as did their green and brown leaf substrates. Moreover, at this time I cannot rule out a role for minimizing predation due to the effects of mimicry and aposematic coloration of yellow morphs. However, there are no syntopic unpalatable yellow dendrobatids in Kaieteur National Park, except the much larger, terrestrial, and toxic *Dendrobates tinctorius* which has much yellow on its dorsum (Bourne et al. 2001).

TABLE 1. Characteristics used to assign 180 golden frogs, *Colostethus beebei*, to five discrete polymorphic types (color nomenclature from Smithe 1975).

Basic color	(N)	Dusky brown stippling	Oblique lateral stripes
*Spectrum yellow	43	suffuse on dorsum	present and distinct
*Spectrum orange	35	absent	present and distinct
*Cream	36	absent	present and indistinct
Buff-yellow	33	just anterior to vent	present and distinct
Spectrum yellow/Brown	33	heavy on dorsum and flank	present and distinct

*brilliant morphs

In addition to search image disruption accruing from color-pattern polymorphism and crypsis, *C. beebei* relied on rapid jumps combined with either hiding or death-feigning behaviors to minimize predation. The antipredator response of diving-and-wedging in phytotelmata by both adults and tadpoles made it relatively easy for humans to hand capture *C. beebei*. However, as with foliar eggs of other species, those of *C. beebei* were sometimes attacked by larvae of drosophiline (Villa 1980) or phorid flies (Villa and Townsend 1983). Foliar eggs and adults of many species of arboreal frogs are also eaten by graspid crabs (Hayes 1983; Krügel 1993) and colubrid snakes (Duellman 1958), as I observed for *C. beebei*.

In conclusion, this observational study of color morphs, predator avoidance, and foraging behavior in a bromeliad-specialist dendrobatid frog, *C. beebei*, suggested that it had at least five color morphs. These morphs ranged in color from a brilliant orange to cream, and with varying degrees of brown stippling. The base yellow coloration of *C. beebei* was derived from carotenes that faded in captive frogs. Color was restored to frogs by feeding them insects maintained on carotene-rich fortified commercial medium. Color polymorphism may be adaptive in this frog through disruption of predator search images. In addition to the potential benefits due to the disruption of predator search images, brilliantly colored morphs were found more often on green leaves of *Brocchinia micrantha* bromeliads whereas predominantly brown morphs were found on dead brown, basal leaves. Although brightly colored morphs on green leaves were easily detected by humans, all *C. beebei* morphs, as well as green and brown leaves, reflected near-infrared light when examined by infrared color photography. Thus, infrared reflectance may be adaptive because of infrared cryptic coloration. *Colostethus beebei* also relied on vigilance and rapid jumping combined with either hiding behavior or death-feigning to minimize predation. Furthermore, *C. beebei* was an opportunistic sit-and-wait predator whose diet included many small arthropods, but especially mosquitoes and midges.

Acknowledgments.—Financial support for this study came from the Eppley Foundation for Research, University of Missouri-St. Louis (UMSL; Set-Up), UMSL Research Awards, UMSL Small Grant, the University of Missouri Research Board, the National Science Foundation (IBN-9630428), Conservation, Food and Health Foundation, and ERM Group Foundation. Permission to conduct this study was granted by the late B. Fernandes, Head of the Guyana Parks Commission, the Minister in charge of parks, Hon. G. Teixeira, and Mr. Fernandes' successor, Mr. C. Rogers. Malcolm and Margaret Chan-A-Sue coordinated my travels to Kaieteur National Park. I thank T. C. Bergquist, H. Carden, A. C. Collins, G. Komlos, C. L. McCarthy, and H. York for field assistance. B. Duncan and M. Jones provided husbandry assistance. T. C. Bergquist, C. M. Bourne, S. H. Braude, J. P. Caldwell, A. C. Collins, M. A. Donnelly, D. B. Tobin, three anonymous referees, and G. Köhler and T. Grant provided constructive comments on earlier drafts of this paper. The Smithsonian Institution expedited research and voucher specimen export permits acquisition through the University of Guyana.

Time in Captivity as a Confounding Variable in Herpetological Research: An Example from the Metabolic Physiology of Treefrogs (*Scinax*)

The study of ectothermic tetrapod physiology and behavior frequently utilizes comparison among related species (Huey 1987). Such research may include the use of animals kept in captivity for variable periods of time; moreover, animal maintenance in the lab may be part of experimental protocols. A common assumption related to this approach is that the physiological or behavioral responses of interest are either unaffected or affected in a similar way by time in captivity. However, we argue that time in captivity may be a potentially influential variable, and that the above assumption may be invalid under a variety of circumstances. We support our argument with data on oxygen consumption of hylid frogs in the genus *Scinax* (Duellman and Wiens 1992).

Oxygen consumption relates to energy expenditure and is one of the most informative physiological parameters in herpetology (Pough et al. 1992). The data presented here were obtained in the context of a study of the evolutionary physiology of *Scinax*, and have been used collaterally to examine hypotheses regarding time of captivity. Our research involves routine measures of standard metabolic rate (resting at a given temperature) and during intense forced locomotion. We attempted to test frogs within two weeks of capture, but this was not always possible. Because the time interval preceding metabolic measurements varied, our data allowed for study of the relationship between time in captivity and metabolic rate. Despite some limitations of the data when analyzed in this context, we report conspicuous patterns that illustrate a useful point in the study of amphibians, many of which are very sensitive to physical changes in their milieu.

We report data on males of five *Scinax* species that are common in southeastern Brazil: *Scinax crospedospilus* (mean body mass ± SE, 1.59 ± 0.028 g; N = 10) is very active and inhabits ponds and lakes in the Atlantic forest or somewhat disturbed habitats; *S. fuscovarius* (4.04 ± 0.096 g; N = 14) is a large and widespread species, and occupies various lentic habitats; *S. perereca* (3.01 ± 0.051 g; N = 16) is found near permanent ponds in open areas or forest borders; *S. g. perpusillus* (0.36 ± 0.010 g; N = 20) reproduces in bromeliads and requires rather well-preserved patches of Atlantic forest; and *S. hiemalis* (0.84 ± 0.008 g; N = 32), which calls mainly in the winter and lives near rivulets that are used for reproduction. In the laboratory, frogs were maintained in individual plastic containers with moist paper towels and artificial vegetation. Photoperiod was 12:12. Diet varied with body size and consisted of crickets, fruit flies, cockroaches, and mealworms.

Metabolic rate was measured between 10 and 30°C using standard techniques (Navas 1996). Standard metabolic rate was measured before 1700 h. Briefly, frogs were placed in humid and aerated chambers, and maintained at the experimental temperature for 2 h. Flow rate was set to maintain pre-experimental oxygen concentration inside chambers at 20.95%. Chambers then were closed for 2 to 6 h, and subsequently re-opened and washed with fresh air. The resulting air mixture was then expressed across a Drierite-Ascarite filter into a Sable Systems PA-1 oxygen analyzer at 130 ml/min, and metabolic rate was calculated from the integrated area under the curve of oxygen concentration versus time (Bartholomew and Lighton 1986) using Datacan 3.0 (Sable Systems). Activity metabolism was measured after 1800 h with a similar approach, but using smaller rotating chambers made out of 50 cc syringes and limiting tests to 3.5 min. Data were log-transformed to improve homoscedasticity and normality.

To isolate effects of time in captivity we used residuals of an ANCOVA in which metabolic rate (ml O_2/h) was the dependent variable, and mass (g) and temperature (C) were independent variables. We used regression analysis of the residuals to test for an effect of time in captivity. Given the nature of the data, individu-

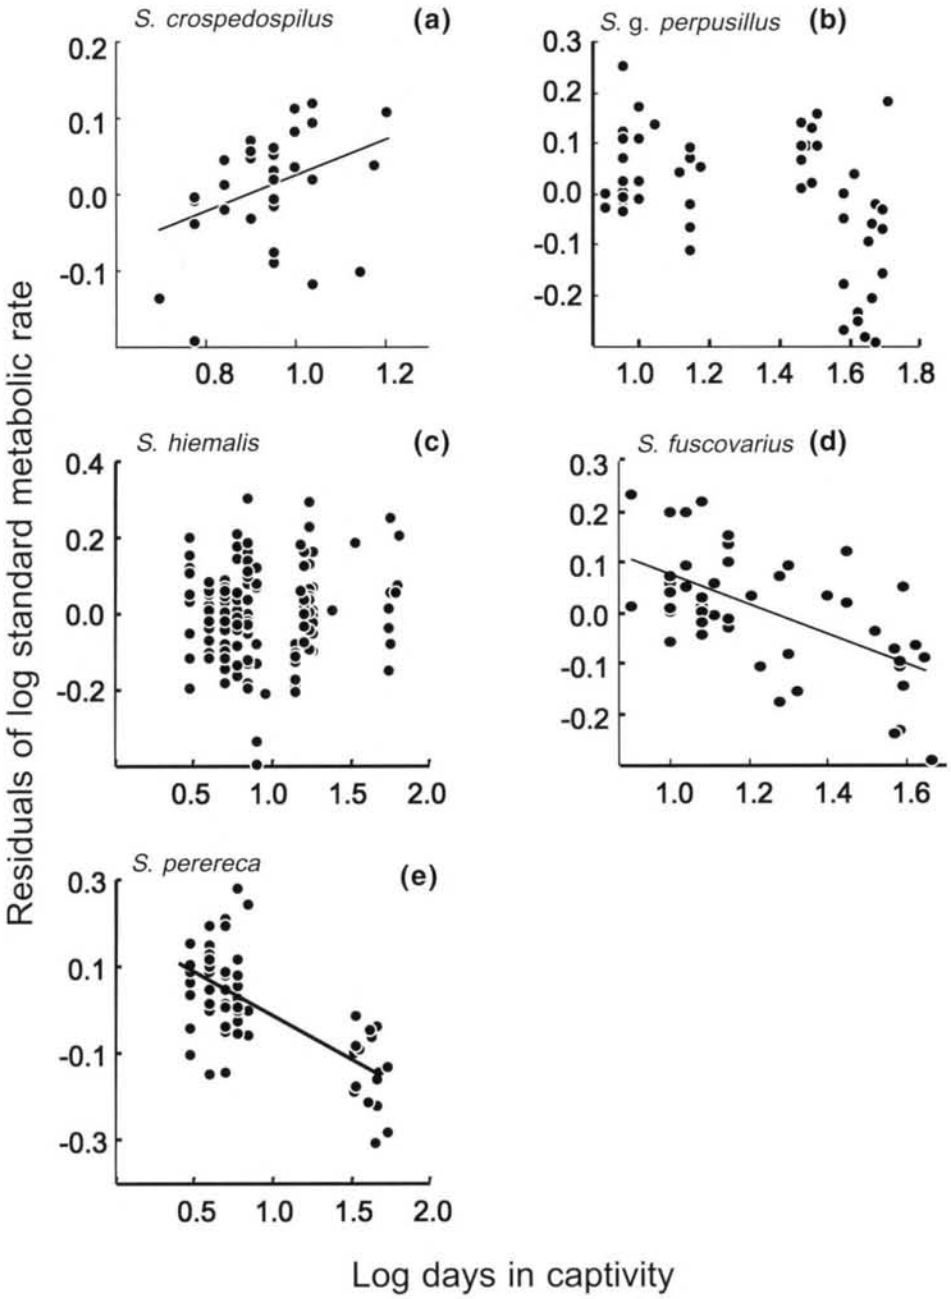

FIG. 1. Residuals of log standard metabolic rate on log body mass and temperature as a function of log-time in captivity in five species of *Scinax*. Regression lines are shown for heuristic purposes and illustrate tendencies of data for which correlation tests are significant. a) *Scinax crospedospilus*, r = 0.486, P = 0.014; b) *S. g. perpusillus*, r = –0.006, P = 0.972; c) *S. hiemalis*, r = 0.145, P = 0.143; d) *S. fuscovarius*, r = –0.472, P = 0.027; and e) *S. perereca*, r = –0.561, P = 0.001.

als exhibiting outlying metabolic rates and measured over a short time interval had a disproportionate influence on overall tendencies. We evaluated this problem using influence plots (SYSTAT 1992) and deleted from the analysis an individual with a very low standard metabolic rate.

Time in captivity related to very different trends of change in standard metabolic rate among species (Fig. 1a–e). *Scinax crospedospilus* (Fig. 1a) showed an increased standard metabolic rate, *S. g. perpusillus* (Fig. 1b) and *S. hiemalis* (Fig. 1c) showed no obvious pattern, and *S. fuscovarius* (Fig. 1d) and particularly *S. perereca* (Fig. 1e) exhibited a significant reduction in standard metabolic rate. Similar trends were absent when activity metabolic rate data were analyzed. Accordingly, time in captivity may influence in different manners the metabolic status of even congeneric sympatric species, but we do not know whether the observed changes involve return to, or departure from a normal situation. Simple general explanations, such as seasonal variation or differences in the rate of physical deterioration, do not hold. Metabolic

rate is related to season in some temperate frogs (Rome et al. 1992) and at least one subtropical anuran (Glass et al. 1997). However, *S. hiemalis* remained longest in captivity, was sampled at different times of year, and its rate of metabolism did not change in captivity. Additionally, loss of body mass, which would reflect physical decay, was not reported for any species during standard metabolic rate measures.

In some anuran species, capture and transport to the lab raises plasma corticosterone, and also may reduce circulating sex steroids (Coddington and Cree 1995; Paolucci et al. 1990). Experimental manipulation of these hormones is coupled with changes in energy expenditure in birds (Wikelski et al. 1999) and calling behavior in frogs (Penna et al. 1992). Because of their effects on behavior, plasmatic corticosteroids and sex-hormones may be part of a control mechanism for energy expenditure (Marler and Ryan 1996). It is possible, then, that the patterns reported in our study are related to captivity-induced hormonal and behavioral shifts that vary from species to species. These patterns may be affected by interspecific differences in energetic status at time of capture, and may lead to different metabolic trends according to the intensity of stress responses to changes in surrounding milieu, reduced social stimulation, or others.

Independent of the nature of the metabolic changes observed, the message we convey is that captivity may induce species-specific changes in amphibian physiology and behavior. Accordingly, researchers should not assume homogeneous effects of time of captivity when engaging in interspecific studies. Doing so may add an uncontrolled confounding variable to the study and may lead to equivocal conclusions in diverse research contexts (e.g., Feder et al. 1984). An extreme case may occur when individuals of a given species are more likely to die in captivity than others, so that final samples compared are not random. These considerations may be important for taxa other than amphibians and for within-species studies. Any investigation that relies on sequential data from individuals along a significant period of time may need to consider time in captivity as a possible confounding variable. To address this problem, researchers may maintain a detailed record for individuals (including dates of capture and tests), perform preliminary tests, or use experimental designs that consider time in captivity as a potentially confounding variable (e.g., Zolman 1993).

Acknowledgments.—This research was supported by a FAPESP (Research Foundation of the State of São Paulo, Brazil) grant to CAN (95/9378-6) and a FAPESP doctoral fellowship to FRG (00/11802-1). We thank Victor Hutchison for valuable comments on the manuscript.

e-mail: daniel.gist@uc.edu

The European common wall lizard (*Podarcis muralis*) was introduced in Cincinnati, Ohio (USA) circa 1950; a population now exists in southeastern urban Cincinnati covering an area of more than 6 km^2 with an expanding tendency. Hedeen and Hedeen (1999) report the present status and the role of railroad tracks in the natural expansion of the population. Because of the ease with which *P. muralis* can be maintained in captivity, they have been introduced

to numerous other parts of the metropolitan area. Some of these subpopulations have persisted. Presently, reproducing subpopulations are found in the Eden Park and Fairview Park areas of the city. J. G. Davis, (Cincinnati Museum of Natural History, pers. comm.) mentions a population on the grounds of the Cincinnati Zoo. Conant and Collins (1998) listed a population in Van Wert County, Ohio, 190 km north of Cincinnati, from which a voucher specimen is available at the University of Kansas Natural History Museum (KU 206727). Recently Davis (pers. comm.) was unable to confirm the continued existence this population. Further, the lizards have been released south of the Ohio River in Kentucky by owners of private gardens (Draud and Ferner 1994). Ferner (pers. comm.) confirms this pattern of colonization south of the Ohio River as a continuing process. However, in other, interior parts of its range, population densities are in decline due to habitat destruction as unmortared stone walls are replaced with concrete walls, refuse piles are removed, and other improvements associated with urbanization are made. The lizards and their varying population density have received attention from the popular press (e.g., Eckberg 1989; Snyder 1993). They have also been the subject of scientific investigations ranging from reproduction to behavior (Brown, Gist, and Taylor 1995; Brown, Taylor, and Gist 1995; Hedeen 1984; Hedeen and Hedeen 1999; Kwiat and Gist 1987; Vigle 1977).

The expansion of *P. muralis* in the New World is of interest to European herpetologists because it is known to be an aggressive species with the potential to influence the range of native herpetofauna. For instance, Henle (in Gruschwitz and Boehme 1986), reports *Podarcis muralis* not tolerating *Podarcis sicula* on walls occupied by *P. muralis*. Although walls are a preferred habitat of *P. sicula*, it retreats to grass-covered areas below the walls whenever *P. muralis* is present. C. Bender (pers. comm.) observed that male *P. muralis* attacked adult sand lizards (*Lacerta agilis*), a European species whose SVL exceeds that of *P. muralis* by 45%.

Reported History of Introduction of *Podarcis muralis*

In the local press of Cincinnati, there are several articles from the 1970's to the 1990's providing contradictory information regarding the details of the introduction of the "famous Lazarus lizards" from Switzerland or Italy in the 1940s or 1950s by member(s) of the Lazarus family, a family well-known in Cincinnati. Accounts also vary in the scientific literature. Hedeen (1984) and Hedeen and Hedeen (1999) reported that two *P. muralis* were released by a Cincinnati resident in the backyard of her home in September 1951. Vigle (1977) states the year of introduction as 1948. The animals had been caught during a family visit to Europe in the Lake Como area of northern Italy. Hedeen (1984) found that the climates of Cincinnati and Milan, Italy, only 40 km distant from Lake Como, have almost identical annual temperature and precipitation patterns, and concluded that excellent conditions existed for a rapid settlement of this species. In Europe, *P. muralis* is reported to be the lizard best adapted to live in human settlements (Arnold and Burton 1978).

A Hitherto Disregarded Document

As a reaction to one of the newspaper articles, a member of the Lazarus family, George Rau, wrote a letter to one of us (DG; letter on file at the Cincinnati Museum of Natural History) on 29 June 1989 in which he stated that, as a child, he was the one who brought approximately ten specimens of *P. muralis* to Cincinnati from Lake Garda in the northern lake section of Italy in 1951 or 1952. As part of a study investigating the status of European lacertids introduced in the USA (Deichsel and Miller 2000), GD gained access to this letter during a recent visit to Cincinnati. A review of the letter prompted an assessment of its contents from the perspective of European herpetology and the writing of the present article. In what follows, we list the key statements in the letter followed by our comments.

Approximately ten specimens of the *P. muralis*, obtained from Lake Garda, Italy were released by George Rau at his parental home on Torrence Court in eastern Cincinnati in September 1951 or 1952. About 1958, he released at the same location another ten lizards with "an absolutely solid blue stomach" obtained from the small island of Vedrá off the southwest coast of Ibiza, Spain. He further states that as a consequence of interbreeding between these two groups, progeny with a series of blue spots on the venters resulted. To support this conclusion, he states that he had never observed lizards with blue spots on the venters prior to releasing the ten specimens from Vedrá.

Despite the passage of time, we attribute a higher credibility to the first person statement of Rau that approximately 10 lizards were released in Cincinnati over second-hand accounts that two lizards were released (Hedeen 1984; Hedeen and Hedeen 1999). The collection site of the first group of lizards in the vicinity of Lake Garda, about 120 km from Milan, Italy, identifies their subspecific status as that of the nominate form, *Podarcis muralis muralis*. Judging from their origin, the second group of lizards released by Rau is *Podarcis pityusensis vedrae*, a cyanistic subspecies of the Ibizan wall lizard (Salvador 1986). The home archipelago of *P. pityusensis* is well separated from the natural range of *P. muralis*. Further, analysis of mitochondrial DNA of *Podarcis* (Harris and Arnold 1999) places these two species in different lineages within the genus. In addition, *P. muralis* does not interbreed with a sister species, *P. sicula*. Thus, the likelihood of Cincinnati *P.muralis* interbreeding with *P. pityusensis* seems remote but could be confirmed by DNA analysis.

It is unlikely that *Podarcis p. vedrae* survived in Cincinnati. This lizard normally lives on two small Mediterranean islands (Vedrá <0.5 km^2, Vedranell <0.2 km^2) whose maritime climate differs greatly from Cincinnati's continental climate. Like other subspecies of *P. pityusensis* from small islands, *P. p. vedrae* does not hibernate in the winter and is hence not likely to endure the more severe Cincinnati winters. Dietary factors also may have contributed to their extirpation. Approximately 50% of the diet of a comparable subspecies of *P. pityusensis* is plant material. Salvador (1986) reports that stomachs of *P. p. karlkochi*, a denizen of the neighboring small island of Conillera, contained almost 40% flowers in the month of January. If the diet of *P. p. vedrae* is similar to its con-subspecifics from small islands, then absence of a continuing plant-based food supply during the winter may have contributed to its demise.

A Comment on Ventral Color Polymorphism

Ventral coloration of *P. muralis* warrants further consideration because it is subject to conspicuous variation, ranging from white, greyish, yellow and orange, to red. Such variation is known even

in small, isolated European populations (Dexel 1986) and is reflected in the Cincinnati population. Brown (pers. comm.) investigated a sample of 77 lizards with 88% white, 7% yellow and 5% red venters, but was unable to correlate ventral color polymorphism of the Cincinnati *Podarcis* with allelic variation at 14 allozyme loci. He attributed the absence of allozyme variation to a founder effect, and the results remain unpublished. It is likely that the blue spots on the belly noted by Rau were actually on the flanks. These spots are particularly pronounced on males, and the intensity of these spots is subject to individual, seasonal, and sexual variation (Gruschwitz and Boehme 1986).

Conclusion

As the result of a letter written by one of the individuals involved in the introduction of common wall lizards to Cincinnati, Ohio, we believe we have evidence that the Cincinnati population of *P. muralis*, now covering more than 6 km^2, originated from ten specimens introduced by George Rau approximately fifty years ago. This information may be useful for researchers analyzing genetic variability in this isolate. The introduced lizards originated from Lake Garda, ca. 120 km distant from Milan, Italy. This location identifies the subspecific status as that of the nominate form, *Podarcis muralis muralis*. Another group of lizards introduced by Rau was identified as *P. pityusensis vedrae* and did not survive.

Acknowledgments.—We wish to express our sincere thanks to the following persons: Carolin Bender provided general information on *Podarcis muralis* and made useful comments on the manuscript. Rafe Brown, Jeffrey Davis, and John Ferner contributed details on the *Podarcis* population in and around Cincinnati. The comments of two reviewers improved the quality of this paper.

The Ornate Box Turtle, *Terrapene ornata*, in Southern Indiana

MICHAEL J. LODATO

and

THOMAS K. HULVERSHORN
6014 Indianola Avenue, Indianapolis, Indiana 46220, USA
e-mail: tkhulver@iquest.net

The ornate box turtle, *Terrapene ornata*, reaches the eastern limit of its distribution in Indiana, USA (Conant and Collins 1998; Ernst et al. 1994). Here it occurs in two widely separated populations. The larger and better known of these occurs in the sand prairie in the Kankakee Basin in northwestern Indiana (Minton 1972). A single record exists for southern Indiana, from Daviess County, in the southwestern corner of the state, as reported by Minton (1972:168). This specimen was collected on 13 September 1950, "... five miles south of Plainville, Daviess County" (List 1951) and was deposited in the University of Illinois Museum of Natural History collection (UIMNH 18038). Minton accepted this record as valid, presumably because (a) the species had been reported from not too distant colonies to the west in southern Illinois (Smith 1947, 1961); (b) the location was a relatively large area of sand prairie not unlike that in northwestern Indiana where the species is known to occur; and (c) other species of the herpetofauna partial to sand prairies in the Midwest, including those of *Cnemidophorus, Ophisaurus*, and *Pituophis*, have been reported from nearby sandy sites proximate to Daviess County (Minton 1972; Minton et al. 1982).

On 13 May 2000, MJL collected a specimen of *Terrapene ornata* in Steele Township, Daviess County, 7 km north of the town of Washington, and about 1 km west of Indiana State Route 57. This turtle, an adult male, was found sliced in two by an agricultural disc at the margin of an area of rank grassland immediately adjacent to a field being prepared for row crops. This specimen represents only the second record of *T. ornata* from southern Indiana, and corroborates List's earlier collection from Daviess County fifty years ago. The specimen has been deposited in the herpetological collection at the University of Michigan Museum of Zoology

(UMMZ 226738).

It is noteworthy that both of the southern Indiana specimens of *T. ornata* came from Steele Township in Daviess County. List's original collection was of a turtle found on Indiana Route 57 (J. C. List, pers. comm.), while the most recent specimen was collected about 1 km west of Indiana Route 57. When plotted on a DeLorme topographic map (Indiana 1998:49, 56), the two collection stations nearly overlie each other, and we surmise that the two specimens were part of the same relict population. This portion of Daviess County consists mainly of gently rolling to flat plains, with sandy soils. There is intensive agriculture, with melon production, orchards, and various row crops. The area from which both specimens of *T. ornata* were collected is a small zone of some fairly well-developed dune topography, where current land use includes pasture in small tracts, perhaps only a few hectares each. The persistence of *T. ornata* at this site over the last half century is remarkable. Other species collected or observed by the authors at the site where *T. ornata* was taken include the following: *Bufo fowleri, Hyla versicolor* complex, *Pseudacris crucifer, Pseudacris triseriata, Scaphiopus holbrookii, Rana clamitans* and *Rana utricularia, Eumeces fasciatus, Coluber constrictor, Elaphe obsoleta, Heterodon platirhinos, Lampropeltis calligaster*, and *Thamnophis sirtalis.*

The Indiana Department of Natural Resources (IC 14-22-34 and Rule 312 IAC9-5-4) lists *Terrapene ornata* as endangered within the state. While not officially listed as endangered or threatened in adjoining Illinois, populations there are apparently now much reduced. Smith (1961) once observed that ". . . the species is common in many parts of Illinois." However, Phillips et al. (1999:162), commenting on its population status forty years later, concluded that *T. ornata* was "uncommon to rare in much of its range in Illinois."

A small tract from the area where *T. ornata* was most recently collected in Daviess County was acquired in 1999 by the Indiana Department of Natural Resources for the establishment of a nature preserve by the Division of Nature Preserves (L. Casebere, pers. comm.). The recent discovery of *Terrapene ornata*, a state endangered species, will enhance the value of this site in affording some protection for at least one of the state's rarest vertebrates.

Acknowledgments.—We thank Robert Ballard, Scott Dugas, and Mel Lodato for field assistance. Lee Casebere and Catherine Smith of the Indiana Department of Natural Resources, Greg Schneider of the University of Michigan Museum of Zoology, and Chris Phillips of the Illinois Natural History Survey provided technical and other assistance.

Gender-specific studies require an accurate technique for sexing individuals. Research on the red-backed salamander (*Plethodon cinereus*) has included many studies that may have gender-biased results, including homing abilities (e.g., Kleeberger and Werner 1982), territorial and agonistic behavior (e.g., Jaeger 1984; Jaeger et al. 1986), and reproduction (e.g., Sayler 1966). Some recent studies have focused on interactions between males and females (e.g., Guffey et al. 1998; Gillette et al. 2000). Sexing adult salamanders using external characteristics is relatively simple when the animals are in courtship condition. Males have mental glands (visible as a whitish area on the chin), square snouts (due to enlarged premaxillary teeth), and a whitish, slightly enlarged region immediately lateral to the cloaca. Females, however, have rounded snouts, lack mental glands, and have no whitish region around the cloaca. The eggs of gravid females are easily visible through the abdominal wall once they reach a diameter of approximately 2 mm. External morphology, however, is not reliable when males are not in breeding condition, and it cannot be used on sexually immature animals.

Sexing animals by invasive internal inspection (e.g., Jaeger et al. 1982) has obvious drawbacks for behavioral or field ecological studies. Quinn and Graves (1999) suggested using the distance between nares at the tip of the snout (inter-nares distance: IND) to sex red-backed salamanders because it is sexually dimorphic and does not change with breeding condition. In the sample examined by Quinn and Graves, however, there was small (0.03 mm) overlap between sexes in the IND; six of the 95 salamanders identified

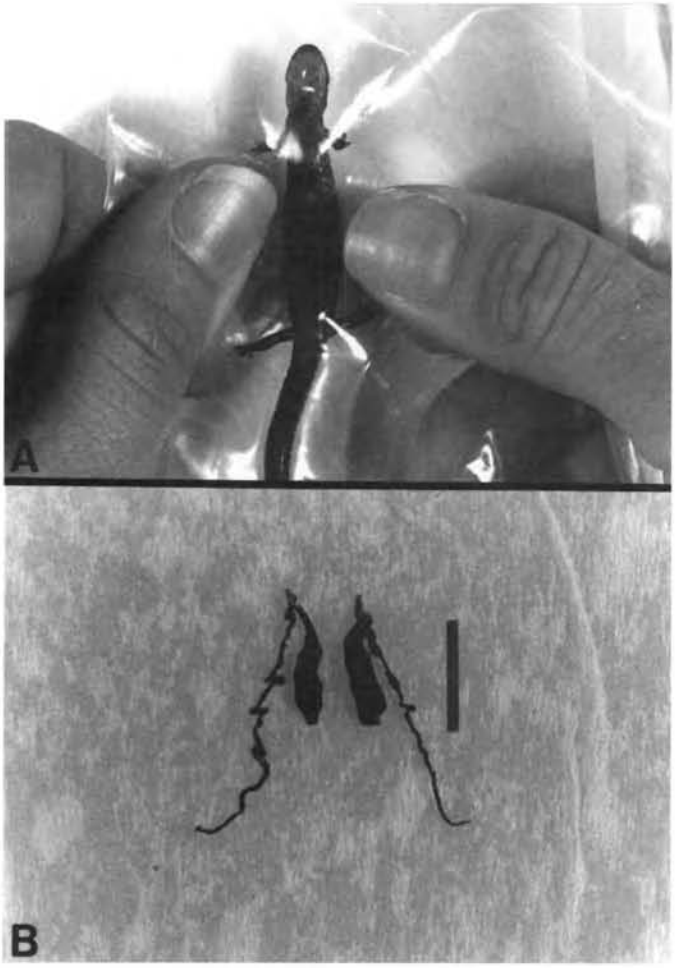

FIG. 1A. Correct position of a salamander to be candled. Thumbs and index fingers should grip the clear plastic bag on either side of the abdomen and gently flatten the animal. B. Testes and vas deferens from a salamander as they appear in an intact animal. Scale bar = 5 mm.

fell into the range of overlap. This suggests that there is a 6.3% chance of making erroneous sex determinations if they are based solely on IND. Furthermore, measuring the IND on a non-anesthetized, live salamander may be difficult. We present here an unambiguous, quick, and non-lethal method for sexing red-backed salamanders by a process generally known as candling.

Candling red-backed salamanders can be used as a reliable means of determining sex because internal organs, particularly the testes (in males), eggs (in females), and intestines, are easily visible through the abdominal wall in a slightly compressed animal that is illuminated from behind. Because candling renders the animal effectively transparent, dissection is unnecessary. We have used this technique for over three years, during which time we have accurately determined the sex of 3000 red-backed salamanders, both in the forest and in the laboratory.

To sex a salamander, we first place it in a small, clear plastic bag. We then manipulate the salamander until its abdomen faces toward us and grip the bag between thumbs and index fingers on either side of the lower abdomen. Next, we gently flatten the animal by stretching the plastic between our fingers (Fig. 1A). This restricts the movements of the animal and compresses it so that light may pass through the abdomen. Stretching the bag immobilizes the animal and increases visibility of its internal anatomy, but too much pressure can cause serious internal damage. Finally, we hold the animal up to a light (e.g., the sun, a flashlight, a standard electric light, or even an overcast sky) so that the light shines through the animal and we can view its internal anatomy through its abdomen. With some manipulation, it is easy to determine in adults (>35 mm snout–vent length (SVL)) whether testes are present or absent; if absent, the animal is female. In gravid females, eggs (as small as 1 mm) appear as whitish circles along either side of the abdomen. Females may have 1–16 eggs, with the average being 7–8 (Sayler 1966). Occasionally, transparency may be greatly reduced by large quantities of material in the gut. In such cases, the animal can be held in a laboratory for a few days until its gut has cleared.

Testes and vas deferens that have been removed from a red-backed salamander illustrate their relative positions to each other (Fig. 1B). The vas deferens is a convoluted tube originating at the anterior tip of the testes, curving posteriorly, and ending at the cloaca, where the sperm are delivered. Although the vasa are not easily distinguishable from the testes while within an intact salamander, they are sometimes visible. Within the body cavity, testes are positioned side-by-side, but their general appearance may vary. However, testes are always in pairs, and are the only paired, black structures in the lower abdomen. Fecal matter, if present, appears as a single black pellet in the lower abdomen and, unlike testes, will break into small pieces if manipulated. If the animal is not aligned so that it is straight from snout to cloaca as it is held in the bag, the testes may not be lateral to each other (i.e., one may be more anterior than the other). However, with gentle manipulation, it is possible to bring both testes back to their normal positions.

The testes of most adult males are obvious and are typically black, large, and slightly pointed on both ends (Fig. 2A). In some

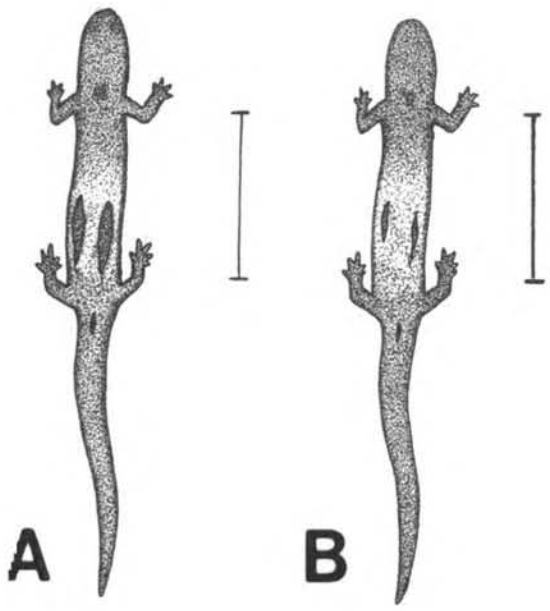

FIG. 2. Relative position and size of testes in red-backed salamanders. A. Most adult males have large, easily detected testes. B. Some testes may be shorter and narrower than others. Scale bars = 20 mm.

adult males, however, often including those held in the laboratory for extended periods of time, testes are relatively short and narrow (Fig. 2B). Testes of immature males (generally < 35 mm SVL) can be more difficult to detect but are identifiable with practice. Such testes have reduced amounts of pigmentation and thus appear gray, with the amount of pigmentation increasing as the animal matures. The testes of immature males are also proportionally much narrower and shorter than those of adult males. We have identified testes in males less than one year old and as small as 22 mm SVL. Ultimately, the appearance of testes represents a continuum, and some may be intermediate to those described in this manuscript.

This technique should prove effective for many researchers requiring a quick, reliable, non-lethal method for sexing red-backed salamanders. In addition, although the specific details concerning male internal morphology may not be applicable in all other salamanders, candling may prove to be especially useful for researchers who wish to sex other species, especially light-bellied plethodontids. With practice, accurate sex determination using this method can take just a few seconds per animal. This simple technique may not only encourage more studies that examine behavioral and ecological differences between male and female red-backed salamanders, but may also spur new research on other species of salamanders.

Acknowledgments.—We thank Robert Jaeger, Deanna Olson, and two anonymous reviewers for critical comments on earlier versions of this paper. We are very grateful to Ryan Taylor and Scott Smyers for providing the illustrations and photographs (respectively), to Chris Swart for advice and for conducting dissections, and to Victor Townsend for assistance with the figures. We also thank Henry Wilbur for permission to conduct research at Mountain Lake Biological Station. In 1997, we began to inventory and monitor amphibians and reptiles at the Chatthin Wildlife Sanctuary in north-central Myanmar. One objective was to obtain seasonal activity patterns and abundance estimates of the sanctuary's herpetofauna. Drift-fence arrays seemed a likely method to obtain some of these data.

Aluminum flashing is widely used in the United States for drift-fences (e.g., Corn, 1994). Such material is unavailable or prohibitively expensive in developing nations. It also is costly to transport, i.e., excess baggage charges. Searching for a substitute, one of us (GRZ) read Enge's discussion (1997) and recommendation of silt fencing, and decided to use it, at least for the first year, in the Chatthin herpetofauna monitoring project. Although not avail-

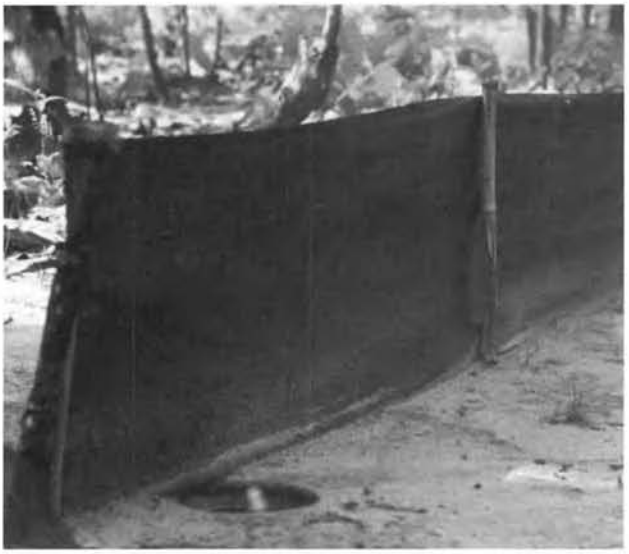

FIG. 2. One arm of the upland array, photographed 6 May 2000, 33 months following fence installation.

able in Myanmar, 100 ft rolls are easily transported in luggage and inexpensive to purchase stateside.

The question of durability remained a major concern. We can now report its high durability and recommend its use. We erected three Y-arrays in early August 1997. The arrays used the local pottery water containers (Fig. 1) as pitfall traps and stakes from locally cut saplings. We stapled the silt fencing to the stakes. As of 6 May 2000, the drift fences are in good condition (Fig. 2) and will remain in operation for one more field season. Each array was placed in a different microhabitat within the dipterocarp forest of the Sanctuary. Canopy cover at the three sites range from approximately 50 to 80%, so the fencing is exposed to some sunlight each day. Temperatures range from daily highs of 45° to 46°C in the premonsoon season to nocturnal lows of 5° to 6°C in midwinter. All sites experience sheet flooding during the heavy rains of the monsoon, one site even in moderate rains. In spite of the range of weather conditions, the silt fencing has not torn or frayed and has not been damaged by large animals.

The arrays have proved a valuable sampling tool, especially for inventorying frogs and lizards and monitoring seasonal movement of these animals. From the beginning, we placed funnel traps, constructed of window screen, at the end of each arm of the array. These traps captured a variety of the larger snake species. The funnel and pitfall traps are opened at the beginning of each month for seven days and checked twice each day, about one hour after sunrise and one hour before sunset. The pitfall pottery usually must be bailed out each morning and evening during the monsoon. When not in use, the pitfalls are covered by a board held in place by a brick; the funnel traps are flattened and stood upright.

Our success recommends silt-fencing drift fences for field studies at other tropical sites.

Acknowledgments.—We thank the entire Chatthin W. S. staff for their support of our field studies and especially the members of the education and ranger teams for their assistance in the initial installation of the drift-fence arrays. U Khin Maung Zaw, U Myint Aung, and U Uga of the Nature and Wildlife Division, Forestry Department, Myanmar, have encouraged us and have provided administrative and personal support for our inventory and monitoring projects. Financial support has been provided by British Airways and the Smithsonian's National Museum of Natural History Biodiversity Inventory and Survey Program. C. Wemmer is a constant source of encouragement; he offered valuable guidance in establishing the Chatthin program.

The Visible Implant Elastomer Marking Technique in Use for Small Reptiles

KRISTEN M. PENNEY*

Mark and recapture studies are used widely in ecology to facilitate the collection of demographic information. Mark and recapture studies of amphibians and reptiles have employed several marking techniques, such as toe clipping (Clarke 1972; Donnelly et al. 1994), scale clipping (Blanchard and Finster 1933; Brown and Parker 1976), shell notching (Cagle 1939), subcutaneous dye injecting (Donnelly et al. 1994), external skin dying (Brown 1997), external fluorescent skin dusting (Nishikawa and Service 1988), tattooing (Joly and Miaud 1989–1990), branding (Clark 1971; Sutton 1996), and internal and external tags such as Passive Integrated Transponders (PIT tags) (Jemison et al. 1995; Prentice et al. 1990) and coded wire tags (Beukers et al. 1995; Hale and Gray 1998; Maynard et al. 1996). Often, body size or anatomical features of the study organism limit the choice of marking techniques. For example, toe clipping is practical only for organisms with several digits and dye injection for organisms that have sufficiently translucent skin. The options are especially limited for marking small species.

We have been involved in a relatively long–term mark and recapture study of the federally threatened sand skink, *Neoseps reynoldsi* Stejneger, in which we have monitored the persistence of individuals on research sites. The sand skink is a small, slender, fossorial lizard with maximum snout–vent length of about 68 mm and a maximum total mass of about 3 g (Conant and Collins 1991). The sand skink has four reduced limbs, with only one toe per front limb and two toes per hind limb. The sand skink's small size, fossorial habits, and limb reduction render most marking techniques virtually useless. PIT tags are too large to implant safely, toe clip-

ping yields only a few unique marks, and external paint marks rub off in the abrasive sand through which the sand skink travels.

The only marking technique that has been used with some success on the sand skink is branding (Hill 1999; Sutton 1996). In 1995, when we began our research on the sand skink, we judged branding to be the best available marking technique. Branding was judged to be more useful than other techniques because brands could be very small and would not rub off. We discovered that branding was not useful for relatively long–term studies, however. Brands became difficult to read over time because of shedding and growth (Hill 1999; Sutton 1996), and remained readable for six months or less in fast growing juveniles (Sutton 1996). We required an alternative marking technique for our relatively long–term study, and we selected the injectable Visible Implant Elastomer (VIE) marking technique. Here, we explain the use of the VIE technique to mark the sand skink, and compare safety, reliability, ease of use, and cost of the VIE technique to the branding technique that we employed previously.

FIG. 1. Diagram of marking locations on the sand skink.

VIE, a fluorescent marking material, was developed by Northwest Marine Technology, Inc. for marking juvenile migratory fish for later identification. VIE also has been used for marking other aquatic or partially aquatic organisms, such as juvenile crustaceans and larval and adult anurans (Table 1). The marking technique involves mixing a liquid elastomer with a curing agent, placing it in a syringe, and injecting a small amount (approximately 1 µl) of the mixture subcutaneously. The mixture hardens within a few hours into a flexible mark. Often, the mark can be recognized with the unaided eye or, if necessary, through polarized glasses under black light. At present, the elastomer is available in four different fluorescent colors, green, orange, pink, and yellow. By using multiple positions on the body and different color combinations, it is possible to mark hundreds of individuals uniquely.

We needed to ensure that the VIE marking technique was effective and innocuous before applying it to the rare sand skink. We used the common ground skink, *Scincella lateralis* Say, a species similar in body size to the sand skink, to examine survival, behavior, and mark visibility. Six individuals were marked and maintained in the laboratory for six weeks. All individuals survived the procedure and retained readable marks for the six–week period. No change in behavior or locomotory ability was observed. Although the marks were seen more easily through the light ventral skin, marks also could be seen through the more darkly pigmented dorsal skin when illuminated by black light.

Following successful preliminary testing of the VIE marking technique, we began marking individuals of the sand skink in 1998. Each captured individual was cooled until it no longer exhibited a righting response and then injected with the elastomer at fixed positions on the body. We chose six separate fixed positions on the ventral side of the sand skink for marking, but limited the number of marks on an individual to three (Figure 1). We have used the VIE marking technique on more than 250 individuals over three years (1998–2000).

We examined our ability to identify recaptured individuals and, when present, the extent of mark migration. We found after one year that the pink elastomer appeared yellowish to the unaided eye on 3 of the 28 recaptured individuals (10.7%) that had been marked with the pink elastomer. The same problem was noted in two earlier studies with other organisms (Godin et al. 1996; Willis and Babcock 1998). We could easily distinguish the pink color with a black light, however. Although we found that some individuals experienced minor mark migration from the exact injection point after one year, it did not reduce our ability to identify them. We suspect the mark migration was caused by growth of the individuals, because most individuals that experienced mark migration were juveniles or small adults when marked. We found after two years that most marked individuals still were readily identifiable. We recaptured 13 individuals that had been marked for two years and the marks of 12 of these individuals were readable. Obvious mark migration occurred in six of the 13 individuals, but in only one case did migration render the marks unreadable, because the marks had broken apart and dispersed widely. We suggest that mark migration is more likely to occur the longer an individual is marked. If care is taken to separate marks widely, misidentification because of mark migration can be minimized.

Because we used branding in previous mark and recapture studies of the sand skink, we compared safety, reliability, ease of use, and cost of the branding and VIE techniques. We judged safety by the apparent effect of the techniques on health and survival of marked individuals. We judged reliability by our ability to recognize recaptured individuals. We judged ease of use by the time it took us to train others to use the techniques.

The VIE technique appeared to be at least as safe a technique as branding. We observed no increase in mortality or weight loss when we began using the VIE technique. The VIE technique makes infection less likely than branding, is less invasive, and allows for quicker healing. Branding leaves a relatively large wound and even carries a risk of burning through the body wall. Despite the relative safety of the VIE technique, care still needs to be employed in using it. Inserting needles to inject the elastomer raises the possibility of introducing and/or transferring infection. To avoid this possibility, we suggest wiping needles with alcohol or changing needles before new individuals are marked. We observed no signs of infection of recaptured sand skinks marked with the VIE technique.

The VIE technique appeared to be a more reliable technique than branding. We judged relative reliability first by comparing recapture frequencies in years (1995–1997) when branding was used as the marking technique and in years (1998–2000) when VIE was used. If the two techniques were equally reliable, then using the same capture regime would yield equal recapture fre-

TABLE 1. Comparison of previous studies that have used the Visible Implant Elastomer (VIE) marking technique.

Study	Species	Size range of marked individuals	Maximum length of study	Percentage mark retention	Changes in survival	Multiple marks/colors	Mark recognition	Other
Bonneau et al. 1995	bull trout (*Salvelinus confluentus*); cutthroat trout (*Oncorhynchus clarki*)	bull trout: <100 to >400 mm; cutthroat trout: <200 to >200 mm	4 months	2 months 100% 4 months 98.8%	not measured	yes/?	not measured	
Dewey and Zigler 1996	bluegill (*Lepomis macrochirus*)	juveniles 34–55 m; adults 73–133 mm	6 months	99% in lab	"no effect"	yes/yes	"good field recognition 98%"	No growth effect (p>.05)
Haines and Modde 1996	Colorado squawfish (*Ptychocheilus lucius*)	average 48.9 mm	142 days	85%	No different than other tested techniques (no p value given)	no/no	some problems noted after 142 days	No difference in predation (p = .20) between marking techniques
Uglem et al. 1996	Lobster (*Homarus gammarus*)	20–24 mm carapace length	16 weeks	100%	92%	yes/yes		little tag migration
Godin et al. 1996	Shrimp (*Penaeus vannamei*)	juvenile = 1.63 g; adult = 38.22 g	10–14 weeks	juvenile 100, 99.9%; adults 100%	juvenile 90.5%, 93%; adults 92.6%	no/yes		differences in tag color recognition
Fredrick 1997	7 species of reef fish	8–55 mm	lab 76 days; field 130 days	lab 100%; field: 2 individuals observed last day	not measured	no/yes	some recognition problems	
Haines et al. 1998	razorback suckers (*Xyrauchen texanus*) Colorado squawfish (*Ptychocheilus lucius*)	X. texanus = 127 mm; *P. lucius* = 150 mm	15 months			yes/yes	*X. texanus* 74%; *P. lucius* 60% after 11 months	did not believe this technique was suitable for their species in excess of 1 year

TABLE 1. Continued.

Willis & Babcock 1998	snapper (*Pagrus auratus*)		2 weeks	93%	100%	no/yes	difference between color recognition
Linnane & Mercer 1998	lobster (*Homarus gammarus*)		3 molts	1.5 months old 100%; 7 months old 100%	1.5 months old 68%; 7 months old 97%		some tag migration
Hale & Gray 1998	brown trout (*Salmo trutta*) and rainbow trout (*Oncorhynchus mykiss*)	*S. trutta* (142–254 mm); *O. mykiss* (80–314 mm)	24–30 days	94–99%	not measured	yes/yes	
Bailey et al. 1998	salmon (*Oncorhynchus kisutch*)	mean length 108 mm	7 months	73%	not measured		
Anholt et al. 1998	Larval anurans (*Rana lessonae* & *R. esculenta*)	≥ 8 mm	5 weeks maximum	85%	100%	yes/yes	no difference in predation (two separate tests; $p = 0.65$, $p = 0.4$)
Malone et al. 1999	*Coryphopterus nicholsii* *Lythrypnus dalli*	*C. nicholsii* 30–40 mm; *L. dalli* 20–30 mm	short lab predation test	not tested	not measured	no/no	no difference in survival to predation ($p = .836$, $p = .20$)
Nauwelaerts et al. 2000	Adult anuran *Rana esculenta*		8 months in lab	100%	not measured	yes/yes	some marks decreased in size as much as 20%

quencies, as long as the probability of recapturing a marked individual did not change. For the population we studied, trapping devices (drift fence–pitfall trap arrays) and trapping effort (number of trap–days) remained the same in all years, and no differences in mean frequency of movements or distance of movements, or in immigration and emigration rates, were detected between any pair of years (Penney unpubl.). Recapture frequency of individuals marked with the VIE technique was about twice (30% vs. 17%) that of individuals marked by branding (log likelihood ratios with William's correction to G–tests, $p < 0.001$). Another, stronger, measure of relative reliability is the relative likelihood of identifying marked individuals. Of the recaptured individuals, researchers were unsure of the identity of 18% of branded individuals (Hill, unpubl.), but unsure of the identity of only 1% of individuals marked with the VIE technique. Both measures of relative reliability indicate that the VIE technique facilitated better recognition of recaptured individuals than branding. This difference probably arose because brands tend to become less recognizable with time (Sutton 1996).

The VIE technique clearly was easier to master than branding. Learning how to inject the elastomer correctly took less time than learning how to brand individuals correctly, and it caused less harm to individuals in the process. Branding was difficult to master, and individuals may have been injured while researchers learned the technique (Sutton, pers. comm.). Neither technique could be used very easily in the field because they both required ice to immobilize individuals.

The startup cost for branding was less than that for the VIE technique. The hand held cauterizers used for branding cost about $10 each, but a starter VIE kit costs from $425 to $1000. Individual cauterizing units could be used to mark 25–35 individuals before they had to be disposed of (Sutton, pers. comm.), but the $1000 starter VIE kit could be used to mark at least a few thousand individuals. The costs per individual for branding and the VIE technique would be comparable (about $0.40 per individual) if 2000 individuals were marked with the VIE starter kit. The minimum amount of elastomer that must be mixed is more than could be used for marking only a few individuals even when the minimum amount recommended by Northwest Marine Technologies is halved. For this reason, we suggest that the VIE technique probably is cost prohibitive for marking only a few individuals at a time. We were able to keep the elastomer in a liquid state on ice or in a freezer for approximately one week, however, although it sometimes hardened beyond usefulness, and others have stored it in the freezer for two to three weeks (Nauwelaerts et al. 2000).

Our results extend the usefulness of the VIE technique beyond apparent limits. Previously, the VIE technique was thought not to be useful for experiments that extended more than one year (e.g., Haines et al. 1998). Our results suggest that the VIE technique can be reliable for at least two years in some organisms. Previously, the VIE technique has been used, as far as we know, only for aquatic and partially aquatic species. Although the VIE technique has been used to mark the terrestrial phase of anurans (Nauwelaerts et al. 2000), our results demonstrate that use of the technique can be extended to completely terrestrial species.

Acknowledgments.—We thank Disney Imagineering, Inc., and the Disney Conservation Fund for allowing and supporting research on its property. This work was approved by the Institutional Animal Care and Use Committee and was permitted by the Florida Game and Fresh Water Fish Commission and the U.S. Fish and Wildlife Service.

The Writings of Sherman Bishop: Part II. Conservation

TODD W. HUNSINGER
New York State Museum, 3140 Cultural Education Center
Albany, New York 12230, USA
e-mail: Hunsitod@hvcc.edu

The end of the twentieth century was met with a flurry of activity to address issues of amphibian and reptile declines. Herpetologists and conservationists concerned by the growing reports of species losses formed organizations such as the Declining Amphibian Population Task Force (DAPTF) and Partnership in Amphibian and Reptile Conservation (PARC). While these efforts have lead to many studies, status assessments, and advances in species conservation, concern over the loss of habitat for amphibians and reptiles and abuses faced by individual species are not new endeavors. Origins of herpetofauna conservation can be traced to an earlier period. One prominent voice in the attempt to raise awareness of this often-maligned group of organisms was Sherman C. Bishop (1887–1951). Bishop was a prominent herpetologist and naturalist working primarily in New York State during the first half of the twentieth century. Bishop's principal legacy lies in his contributions to the knowledge of the life history and developmental biology of salamanders (Grobman 1952; Hunsinger 2000). What has been overlooked in discussions of Bishop was his passion for species and habitat conservation.

Sherman Bishop addressed issues of conservation in publications, lectures, and personal letters. He also worked very hard to try to educate and raise awareness and interest in the natural history of amphibians and reptiles, particularly salamanders. From his lecture notes on salamanders, Bishop stated in the introduction,

> "Among all the little creatures of the woods and streams none have been so neglected as the salamanders and none are of greater interest. And there still remains the opportunity for those who have the interest and persistence, to make valuable contributions to our knowledge of the group."

Bishop's interests in education and public awareness are exemplified in one of his favorite stories which concerned the mythology that surrounded the Mudpuppy (*Necturus maculosus*), a species that Bishop researched extensively (Bishop 1926). In lectures he relayed the following account:

> "The first salamander I wish to talk about…is the Mudpuppy or water-dog. It should be known as the newspaperman's perrenial [sic] friend, for it provides a news item at least once a year in all parts of the range of the animal. This is always the 'strange animal unknown to science' notwithstanding it was first described in 1799 and given a name in scientific literature as early as 1818.

FIG. 1. Bishop's library stamp, drawn by friend Hugh P. Crisp. This depicts Bishop's array of interests including scientific literature, amphibians, reptiles, fish, spiders, and his boyhood home in the Finger Lakes Region of New York. (Courtesy of Beth Bishop Flory)

> Once while I was at the State Museum in Albany, a reporter for one of the local papers brought to me a living Mudpuppy taken that day in the nearby Hudson. Here I thought, is a reporter that wishes some information and may be expected to tell the truth when he knows it. So I took the time to tell him all about the animal, where they live, what they eat and something about their nearest relatives. Among other things, I told him that their nearest relatives were found in some of the caves of Europe. I looked in the paper the next day and here again was the old story about the 'strange animal unknown to science,' a fish with four legs and with its ear split into three parts and believed by zoologists at the State Museum to be of European origin having reached the Hudson by way of an underground channel from Bavaria."

Bishop lectured on salamanders throughout the northeastern United States during the 1930s and 1940s. In a letter to long-time colleague W. P. Alexander at the Buffalo Museum of Science, dated 19 May 1937, Bishop wrote:

> "I will be glad to talk on salamanders. I have given this same lecture in Boston and at fair Harvard where it was received with acclaim at the Boston Society of Natural History and with sadness at Harvard. At the last named institution, my talk revealed to one of the graduate students that he had written a doctor's dissertation dealing with one species of salamanders which he had misidentified and confused with another."

Cornell professor and lifetime friend Albert H. Wright undoubtedly influenced Bishop's interest in conservation. As an undergraduate, Bishop traveled to the Okefenokee Swamp in 1912 with Wright and co-authored his first paper (1915) on the snakes of the region. Wright is credited with helping to preserve the Okefenokee Swamp. Wright's influence is seen in Bishop's first publication on salamanders. In his lengthy account of the four-toed salamander (*Hemidactylium scutatum*), Bishop (1919) cited Wright (1918), who stated, 'The four-toed salamander...is vanishing with the drying up or draining of sphagnum bogs and feather bed swamps." Bishop continued the discussion of habitat alteration by stating, "It is certain that the final conversion of sphagnum areas will mark the extirpation of the species in such localities." It is worth noting that Wright (1918) was writing about the decline of habitat of the Bog Turtle (*Clemmys muhlenbergii*), a species that is currently one of the most imperiled turtles in the northeastern United States. The expanding use of gasoline-powered engines in the early 1900s must have rapidly accelerated the rate of wetland dredging and filling as backhoes and bulldozers were able to make the efforts of men much easier. This obviously did not go unnoticed by Bishop and Wright.

In *The Amphibians and Reptiles of Allegany State Park* (Bishop 1927), Bishop again struck a conservationist tone. In the introduction he stated, "The amphibians are timid and inoffensive. Some, as the toad, are beneficial because of the noxious insects, slugs, etc., that they destroy."

Bishop (1927) also tempered some of the common misconceptions about the impact of nongame species on game species that has been prevalent in state management agencies. He wrote, "A few, the Water snake and Garter snake among them, are harmful when under certain conditions they kill too many valuable food fishes and toads." Bishop's comments were quite benign when compared to those of his colleague Elon H. Eaton. Eaton (1928) wrote, "I believe the water snake should be destroyed by all sportsmen whenever they have the opportunity." Bishop and Eaton were more than just casual acquaintances. They went on collecting trips for Timber Rattlesnakes (*Crotalus horridus*) together in 1925 (NYSM 2623, 2627), and worked summers on the New York State Watershed Surveys conducted by the Conservation Department. Eaton also authored the text *Birds of New York* (Eaton 1910, 1914), published by the State Museum just preceding Bishop's tenure as Zoologist. Despite their close professional relationship, their attitudes towards reptiles could not have been farther apart. Eaton (1928) also wrote:

> "The softshell turtle (*Amyda spinifera*) which inhabits Keuka, Seneca, and Cayuga is a predacious species which frequently feeds on fish. The same is true of the generally distributed snapping turtle."

The account also included a photograph of a snapping turtle with an inscription similar to a federal warrant, stating "Soft shell (sic) turtle (*Amyda spinifera*), enemy of shallow water fish." Although the photo was incorrectly identified, the view towards these species could not be mistaken.

The plight of the Timber Rattlesnake (*C. horridus*) was also of concern to Bishop in his accounts of the herpetofauna of Allegany State Park. It is evident from his remarks that he was fully aware of the dangers that a population faced when confronted with increased human activity. Bishop (1927) wrote in the introduction:

> "The Timber Rattlesnake is found in numbers in several restricted areas in the park and surrounding reservation. Confined, as they are, to the out-of-the-way places where they are not likely to be encountered by the camper and tourist, they may be expected to persist for years as one of the most striking and interesting animals of the region."

Bishop reinforces this sentiment in the species accounts, stating:

> "The Timber Rattlesnake has never been found in any section of the park set aside for the use of campers and tourists. It is therefore not likely to be encountered and can not be regarded as a source of danger to those visiting the region."

In the description of the regions of the park, Bishop again returned to the theme of human pressure on rattlesnakes by writing:

> "Limestone Hollow is locally celebrated because of the work of 'Rattlesnake Pete' of Rochester who secured many specimens from the region."

It is hard to determine if it was Bishop's quest for scientific accuracy (an attribute that was evident in all his work and the review of his work by others) or his naiveté of the extent of the pressures this species faced, but his detailed description of the den areas may have hastened the decline of rattlesnakes in the park. In describing the area of Peters Run he wrote:

> "The cracks and cavities in this conglomerate ledge are noted among the inhabitants of the region as being the denning up place for the Timber Rattlesnake. Peters Run is one of the few localities where rattlesnakes occur in numbers within the park area."

Thirty years later, rattlesnakes were rarely seen in the park. Stewart (1961) wrote about her 1957 field work, "Most of the 'snake stories' that the natives tell of seeing rattlers in the park are from years ago; few people have seen a live rattler in recent years, except near the den sites." Recent work indicates that the species is extirpated from the park and surrounding area.

Bishop was decades ahead of the rest of the northeast in attempts to educate the public and conserve the Timber Rattlesnake.

Many counties of New York State offered bounties on rattlesnakes for many decades after Bishop's account. In the 1940s, the State Conservation Department attempted an experimental eradication program for rattlesnakes in Essex County that involved using dynamite to blast the main den areas (Stechert, in Brown 1993). A high school science textbook in use in New York State (Wood and Carpenter 1938) in the decade following Bishop's remarks stated, "Rattlesnakes, copperheads, and cobras are the worst enemies of man." It was thirty years between Bishop's writings and the next published account expressing concern about the plight of the Timber Rattlesnake in New York (Wright and Wright 1957). It was not until 1984 that the state protected rattlesnakes from the type of extirpation feared by Bishop, long after it had disappeared from Allegany State Park.

Bishop's strongest statements about habitat alteration during his work in Allegany State Park did not appear in his publication, but rather in a letter written to Charles Adams, Director of the New York State Museum. On 18 August 1926 Bishop wrote from his camp:

> "Some fine collecting places have been destroyed in the process of 'improving' the park and among them one of the two known streams for the Red Salamander. It seems to me that conditions might be improved at the park if someone would direct the efforts of the laborers engaged in clearing certain areas for the use of campers."

The Red Salamander (*Pseudotriton ruber*) was taken in the area Bishop referred to on 3 August 1922 (NYSM 3205). Recent attempts to find *P. ruber* in the Park have failed (unpubl. data).

Bishop also acknowledged the decline of the Box Turtle (*Terrapene carolina*) in the greater Albany, New York area. In response to a letter received at the State Museum inquiring about a turtle that had been seen in Victory Mills, New York, Bishop wrote on 13 July 1928:

> "Judging from your interesting account, I believe the turtle you have found is a Box-turtle. Formerly the Box-turtle was common at Albany but the frequent burning over of the sand plains has probably wiped it out."

Fire was a natural occurrence in the Albany Pine Bush prior to European settlement and fire suppression. Although it is hard to tell what role these changes played, if any, in the decline of the Box Turtle, we must recognize Bishop as one of the earliest herpetologists to address the decline of this overharvested species. Bishop (1923a) noted this decline in his accounts on the herpetology of Albany County a few years earlier.

Bishop left the State Museum in August 1928 to take a position at the University of Rochester. His concern for habitat alteration continued to grow during this period. His harshest comments on this topic are found in a letter to Charles Adams dated 12 June 1929. Bishop wrote:

> "The Mendon Ponds area is being developed for park and picnic purpose. I was sorry to see that wide boulevards are being constructed all through the place so that auto tourists will be able to get in and pick all the curious flowers."

A Bog Turtle from Mendon Ponds on 26 June 1931 (NYSM 2220) was placed in the collection of the now defunct University of Rochester Museum of Natural History. This is the only report of their occurrence in the park.

In the same letter to Adams, Bishop continued, "Bergen Swamp, which I visited for the first time last week, is a remarkable place and should be preserved just as it is. I wish you could stop off long enough some time to visit the place with me." Bishop would spend the rest of his life working to ensure the preservation of Bergen Swamp as an active member of the Rochester Academy of Sciences (RAS), for which he served as the president in 1946–1947, and the Bergen Swamp Preservation Society, which formed in 1912. Bergen Swamp is one of only two localities of the Massasauga Rattlesnake (*Sistrurus catenatus*) in the state and supported a population of Bog Turtles during Bishop's life. At the time of Bishop's death it was written in the Museum Service Bulletin (1951) that, "He had been one of the most active supporters of the Rochester Academy of Science and the Bergen Swamp Preservation Society." Bishop was appointed Fellow of the Rochester Museum of Arts and Sciences in 1946 "for his attainments as a scholar, and for his contributions to this community in promoting a broader appreciation of the place of science in life." Bishop's strong interest in conservation was a perfect match for RAS, as its members were instrumental in helping to establish the Everglades National Park as well.

Bishop was a man of many talents and interests. It would be incorrect to categorize him only as a herpetologist, considering that he authored or co-authored more than 100 papers on spiders (Adler 1989) and spent seven summers working on the watershed surveys of New York State documenting fish distribution (see Fig. 1). Due to his diverse, yet accurate, knowledge of the natural world, Bishop has deservedly been called a field naturalist (Adler 1989). His concern for species preservation outside of herpetology was voiced just as strongly. A paper entitled "More Bird Protection Needed" (Bishop 1923b) states in part:

> "An additional large number hunted in and out of season, killing nongame birds and game birds greatly in excess of the legal limit. This is the wholesale drain on the wild life of a limited region; if the record is extended to cover the country, the result is appalling.
>
> In fixing the limits of the reproductive capacity of birds Nature did not take into consideration the automatic shot gun or the ability of man to construct nets and snares."

Still, Bishop's most vocal efforts centered on the effect of habitat destruction on salamanders, a group of organisms he spent his life studying. Bishop (1941) wrote in the introduction to *The Salamanders of New York*:

> "If any justification is needed for the publication of the detailed records accompanying the accounts of the species, it is to be found in the rapidly changing conditions which, in various parts of the state, have brought about the extermination of certain species over wide areas. These changes may be expected to continue and exert an ever-increasing pressure as swamps and marshes are drained, and land cleared."

Bishop was no clairvoyant, yet his prediction of salamander declines in regions of New York are being realized. Recent attempts to locate Mudpuppies in Salmon and Black Creeks (Monroe County) were unsuccessful (T. W. Hunsinger and W. L. Hallahan, unpubl. data, 2000 survey). Bishop (1941) cites many specimens from these localities spanning a decade.

Bishop again took the role of advocate for the study of the natural history of salamanders in the preface to his major work, *Hand-*

book of Salamanders (Bishop 1943). The first lines of the text are an invitation to advance the scientific knowledge of the group. In it he writes:

> "It is hoped that this handbook may be of help to the growing number of persons interested in salamanders and perhaps lead some of them to more detailed studies of many of the forms than I have been able to make."

Sherman Bishop was a rare combination of dedicated scientist with an insatiable thirst for an understanding of the natural world and advocate for species and habitat conservation at a time when few people were thinking about, let alone advancing, the issue. He took full advantage of every opportunity to try to educate others and share his enthusiasm for amphibians and reptiles with any audience. After his death it was written in the Museum Service Bulletin (1951), "With all that he was a very human person who liked outdoor life, and shared his enthusiasm with all who came in contact with him, giving encouragement to the student and amateur alike."

Perhaps the passing of Sherman Bishop was best expressed in a letter from D. L. Gamble of Ward's Natural Science Establishment to Karl P. Schmidt concerning the shipment of Bishop's specimen collection from Rochester to the Chicago Natural History Museum (Field Museum of Natural History) dated 2 October 1951. Gamble wrote, " I miss Sherm Bishop very much. I talked with him just a week or so before his death. His death was a great loss to zoology and we can ill-afford to lose men of his calibre (sic)." Indeed. Bishop's death silenced a passionate voice for the advancement of knowledge and conservation for this group of "neglected" animals, as Bishop frequently referred to them.

Acknowledgments.—I thank Kraig Adler, Robert Daniels, Beth Bishop Flory, Bill Hallahan, Alan Resetar, and Roy McCaig (RAS) for their assistance in researching this paper. Robert Daniels and Kimberley Corwin Hunsinger reviewed drafts of the manuscript and provided insightful comments. This is contribution number 826 of the New York State Museum and Science Service, the last in the series.

**Corresponding author*

We report on the successful reproduction of four species of monitor lizard (*Varanus glauerti, V. kingorum, V. pilbarensis*, and *V. caudolineatus*) maintained by the senior author. All are currently assigned to the subgenus *Odatria* (King and Green 1999). There are no previous literature reports of captive breeding of these species. All species are housed under the same conditions. The animals are kept in pairs or trios in enclosures approximately 130 x 60 x 80 cm (L x W x H), with 30-cm deep substrate (loam and grit), and stacked boards to provide hiding places. Water is added to the substrate in sufficient quantities to ensure that the lower levels are always moist. Temperatures in the enclosures range between 28°C and 66°C, maintained 24 hours a day. Heat is provided by spotlights and heating mats. The animals are fed crickets of various sizes dusted with a 3:1 by volume mix of Rep-Cal® and Herptivite® and small mice. Food is provided generously.

Initial copulations are observed more or less continuously over three to five days. Prior to production of subsequent clutches the

mating period is shorter (about 24 h). Throughout the mating period the pair stay in close contact. Eggs are buried in the substrate, usually at night (despite the 24 h light cycle). They are removed immediately and incubated in a 1:1 mixture by weight of perlite and water. Initially clutches were incubated at a constant 30.6°C. Under these conditions eggs of all species hatched after 90–100 days (exceptionally 65–110 days). Subsequently, incubation temperatures were allowed to fluctuate between 28.5°C and 32.5°C. Incubation times for individual species under these conditions are given below.

Varanus kingorum has been maintained since 1993. During this time six generations of captive animals have been produced. Clutch size is typically two but as many as six eggs have been laid. Up to 14 clutches of eggs have been produced by a single female in as many months. Incubation takes 65–80 days under the conditions described above. Hatchlings have a total length of about 15 cm. Both sexes become sexually mature at four months of age. Males are removed from enclosures after egg laying to allow females to regain condition.

Since 1996 *V. glauerti* have produced a total of five generations of captive bred animals. Females produce up to 68 fertile eggs in eight clutches over eight months; eggs hatch after 90–110 days. Average clutch size is nine with a maximum of 12 eggs. Hatchlings measure approximately 18 cm total length and can reach maturity at around seven months of age. Males are separated from females after egg laying.

Since 1997 three generations of *V. pilbarensis* have been produced. Clutch size averages four eggs, with a maximum of six. Up to six clutches are produced per year, usually laid two weeks apart over 2–3 months followed by a pause of nine months. Eggs typically hatch after 80 days, sometimes as quickly as 65 days. Hatchlings measure approximately 13 cm total length and can reach sexual maturity as early as eight months of age. It has not been necessary to separate sexes after egg laying because females regain condition rapidly.

Three generations of *V. caudolineatus* have been produced since 1997. Typically 5–6 clutches of eggs are produced over four months, followed by an eight month pause. Clutch sizes of 2–3 eggs are common, however a maximum of five eggs have been laid. The eggs hatch between 65 and 80 days and reach sexual maturity at the age of five months. It has not been necessary to separate sexes after egg laying.

Although multiple clutches have been recorded many times in captive monitor lizards (Card 1994; Horn and Visser 1990, 1997; Vincent and Wilson 1999) and occasionally in wild populations (Shine et al. 1996), the numbers of clutches reported here are much higher than those previously reported for any captive monitor lizard. Similarly, the ages at maturity reported here are much lower than those in the literature. The results suggest that, given conditions of almost unlimited access to food and heat, these lizards are capable of much higher rates of growth and reproduction than had been previously supposed. They further suggest a capacity for rates of metabolism that are at present undocumented.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 32, Number 1 (March 2001). Submissions should be directed to one of the section editors (contact information located on inside front cover of this issue), as follows: amphibians (Painter); lizards, amphisbaenians, crocodilians, *Sphenodon* (Hayes); snakes and turtles (Butterfield).

CAUDATA

BATRACHOSEPS STEBBINSI (Tehachapi Slender Salamander). **ATTEMPTED PREDATION.** Examples of predation are known for only a few species of *Batrachoseps*, and none has been reported for *B. stebbinsi*, a species with a very restricted distribution in the Tehachapi Mountains of south-central California, USA (Hansen and Wake, *in press*. *In* M. J. Lannoo [ed.], Status and Conservation of U.S. Amphibians. University of California Press, Berkeley).

On 18 March 2000, two of us (TB, SW) observed a female *Diadophis punctatus* (190 mm SVL) attempting to constrict an adult *B. stebbinsi* (54 mm SVL). Both were located beneath small rocks at the base of a north-facing talus slope. The snake had seized the salamander just anterior to the hind limbs and was attempting to encircle the salamander's body with coils, but with little success. The snake appeared rather thin, perhaps having recently emerged from winter dormancy. After a ca. 15 minute struggle, the salamander dislodged the snake by dragging it down among smaller rock fragments and escaped. This observation was made at 1400 h at an air temperature of 20°C within Caliente Canyon, Kern County, California.

Ringneck snakes readily consume *Batrachoseps* in captivity (Hubbard 1903. Univ. California Publ. Zool. 1:157–170; RWH, pers. obs.). As the distribution of *D. punctatus* overlaps the ranges of most species of *Batrachoseps*, several authors (e.g., Stebbins 1954. Univ. California Publ. Zool. 54:47–124) have suggested that ringneck snakes likely are natural predators.

CAUDATA

CHIOGLOSSA LUSITANICA (Golden-striped Salamander). **REPRODUCTION.** Amphibians display a great diversity of oviposition strategies, laying their eggs in an array of microhabitats. *Chioglossa lusitanica* is a slender-bodied streamside salamander, endemic to the northwestern Iberian Peninsula. This species is reported to lay eggs in small clusters in deeply submerged holes along stream margins, and attached to the undersides of stones or against rocks in slowly flowing water (Arntzen 1981. Amphibia-Reptilia 1:187–203). However, there are actually few reports where these oviposition sites have been described. The first *C. lusitanica* eggs were found in the 1960's in a mine gallery located in the surroundings of Porto (northern Portugal) by Gonçalves (1962. Naturalia 8:1–3). Moreover, in a national survey of the species' distribution, no eggs were found in streams (Teixeira et al. 1999. Estudos de Biologia e Conservação da Natureza. 22. ICN. Lisboa. 33 pp.). In contrast, in some mines it is common to see hundreds of eggs, where clusters from one or more females are found on moist walls and attached to the submerged parts of walls or stones (Arntzen 1981, *op. cit.*; Faria et al. 1996. Livro de Resumos. IV Congresso Luso-Espanhol de Herpetologia: 82).

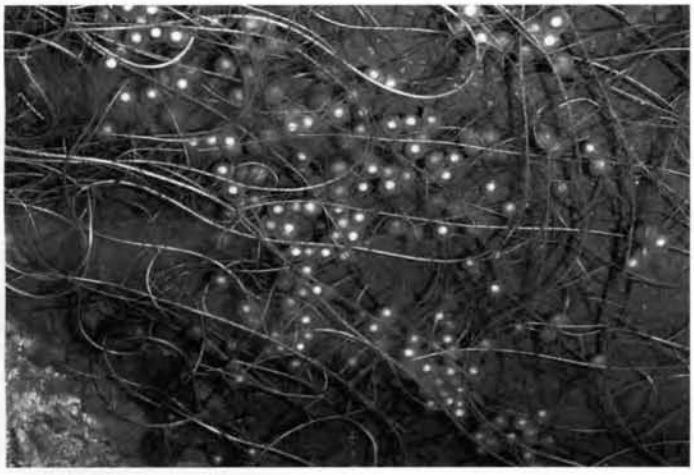

FIG. 1. Egg masses of *Chioglossa lusitanica* submerged among roots of aquatic vegetation.

On 10 October 2000 during a visit to the mine gallery of Inferno or "upper mine" (see Arntzen 1981, *op. cit.* for a detailed description) near Porto (UTM 29TNF45), in addition to the typical egg-laying substrates found in that mine, we observed masses of eggs in mats of submerged roots (Fig. 1). The number of eggs found in the mine during this project, as well as in previous literature reports, are summarized in Table 1.

The visits to this mine showed a similar diversity of oviposition substrate among years. Based on this, and the substantial increase of the number of eggs found in 2000, we hypothesized that the main cause for the observed egg clusters in a different oviposition substrate was because the normal oviposition sites used by *C. lusitanica* females in this mine were already occupied.

TABLE 1. Number of eggs found in the upper or Inferno mine gallery from 1994 to 2000.

GYRINOPHILUS PORPHYRITICUS DANIELSI (Blue-Ridge Spring Salamander). **BEHAVIOR**. Tree-climbing behavior has been reported for relatively few salamander species, and is unknown for members of the plethodontid genus *Gyrinophilus* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.). Herein, we report arboreality in a primarily aquatic and terrestrial salamander, *Gyrinophilus porphyriticus danielsi*.

On 27 June 2000 at ca. 1130 h, two *G. porphyriticus danielsi* were observed in trees in Great Smoky Mountains National Park, North Carolina, USA. The salamanders were found near the convergence of Beech Flats Prong and Peruvian Branch (Clingmans Dome Quadrangle 35°36'N, 83°24'W) at an elevation of ca. 1183 m. The first individual (64 mm SVL) was perched on a snag branching from the trunk of a small red spruce (*Picea rubens*) 82 cm above the ground. The second individual (68 mm SVL) was perched 15 cm above the ground on a horizontal trunk of a striped maple sapling (*Acer pensylvanicum*). At the time of the observation, skies were heavily overcast. Heavy rain occurred the previous night, and rain began again shortly after the observations were made. The air temperature was 19.5°C. Both specimens were within 5 m of the habitat typically reported for adult *G. porphyriticus*: small, rocky seeps that are tributaries of montane streams.

These observations are novel not only because this species has not previously been observed climbing, but also because two individuals were found in trees in nearly the same location and at

essentially the same time. Arboreality may be environmentally or phenologically triggered when conditions are appropriate, particularly during or in temporal proximity of rainfall. Since arboreality has not been reported in any eastern salamander with great frequency, there have been few suggestions as to the cause or importance of this behavior.

These observations were made in conjunction with the USGS Southeastern Amphibian Research and Monitoring Initiative under permits from Great Smoky Mountains National Park (GRSM 00-025) and the North Carolina Wildlife Resources Commission (No. 0100). We thank Lora L. Smith and C. Kenneth Dodd, Jr. for comments.

HYDROMANTES PLATYCEPHALUS (Mt. Lyell Salamander). **BEHAVIOR**. Little information is available concerning the behavior of *Hydromantes platycephalus*, a bolitoglossine plethodontid salamander known only from the Sierra Nevada of California. This is probably due to their nocturnal activity, patchy distribution, and remote, generally high elevation range (up to 3660 m). Discovered by accident in Yosemite National Park (Camp 1916. Univ. California Publ. Zool. 17:11–14), this species is commonly associated with wet granitic talus slopes. Typical microhabitats are downslope from melting snowfields on granite bedrock, usually with a thin film of flowing water and scattered cover consisting of granite boulders. Individuals also have been found under moss on wet rock faces, under pieces of wood, or under rocks on the edges of streams or in moist decomposed granitic soil (Adams 1942. Univ. California Publ. Zool. 46:179–204). In 1999 we discovered a new population at 3500 m elev. in Kings Canyon National Park (36°49'41"N, 118°26'9"W). The site is characterized as glacially carved granite with a small stream (75 cm wide, 1–10 cm deep, flow rate ca. 1.5 m/sec in mid to late summer) flowing over granitic bedrock. The stream flows out of a lake (0.4 ha SA) over a 100 m flat stretch (ca. 4–9° incline), then over a cliff, cascading nearly vertically for 60 m. Salamanders were found under large slabs of granite (60 x 40 x 12 cm) in direct contact with the water and hiding along the edges of the entire waterfall in moist fissures. One specimen was collected at the site in 1999 (MVZ 230961), but other animals were either caught and released, or observed and not handled. We found many more individuals when the site was visited at night (35 in one nocturnal visit versus 15, 7, 4, 8, 13, 9 in six diurnal visits). In diurnal visits, salamanders were found exclusively under large pieces of granite. The animals were in direct contact with the water, on the edge of the flowing stream. No salamanders were found away from the wet areas even though many rocks were turned. In sharp contrast to the diurnal surveys, in the nocturnal survey we encountered salamanders out in the open both in the water and on dry land, sometimes as far as 2–3 m from the stream. Additionally, many of the salamanders were seen clinging to the granite bedrock (with their feet and their tail) in the middle of the stream, usually with their heads above the water surface and the rest of the body immersed. One was crawling upstream along the edge of the stream in the water, but froze in our light, then drifted downstream about 10 m before clinging to the bedrock in the middle of the creek. When startled by our presence, another salamander made a short swim using its tail. *Hydromantes platycephalus* has not been reported previously in lotic habitats, which we believe may be a common habitat type, especially at high elevations (>3500 m) where moisture-retaining soil is sparse or lacking altogether. This behavioral observation stresses the importance of moist microhabitats for *H. platycaphalus* (especially in areas lacking soil) and suggests that the specialized morphology (cupped feet and prehensile tail) may aid the animal in lotic locomotion.

Submitted by **VANCE VREDENBURG, TATE TUNSTALL, HIEN NGUYEN, JOHN ROMANSIC**, and **SEAN SCHOVILLE**, Museum of Vertebrate Zoology, University of California, 3101 Valley Life Sciences, Berkeley, California, USA, 94720; email (VV): vancev@socrates.berkeley.edu.

PLETHODON SERRATUS (Southern Red-backed Salamander). **INTRASPECIFIC AGGREGATION**. On 4 November 2000 we found an aggregate of nine individual *Plethodon serratus* inside a rotting log that was lying on the floor of a ravine covered by deciduous forest in the Cherokee National Forest near Rafter, Monroe County, Tennessee, USA. All salamanders were within 5 cm of all other members of the group. Two of them were small juveniles (< 25 mm SVL), whereas the others appeared to be adults or larger immatures. The log was ca. 15 cm in diameter. The cavity where the salamanders were found was wet although underneath the log was dry. Nine additional *P. serratus* were found under logs in the vicinity (within 100 m), although most logs were also dry underneath. There was never more than a single individual under any of these logs. Several individuals were tightly coiled in a posture to help prevent water loss (Ray 1958. Ecology 39:75–83). There had been no measurable rain for 38 days. The air temperature was ca. 18.5°C, and had reached similar temperatures every day for the previous two weeks.

Overwintering aggregations have been reported for species of *Desmognathus* and *Pseudotriton* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press. Washington, D.C.). In addition, *P. cinereus* has been reported from winter hibernacula in ant mounds (Caldwell and Jones 1973. Am. Midl. Nat. 90:482–485). The relatively warm air temperatures, the number of single-occurring *P. serratus* in the immediate area, and the fact that the salamanders were above ground lead us to believe that we did not observe a winter aggregation. Although *P. cinereus* has been reported to aggregate in small groups for mating (Placyk et al. 2000. Herpetol. Rev. 31:167), the presence of two small juveniles suggests that this aggregation was not related to mating. Due to the dryness of the region and the water-conserving posture seen in several of the single individuals, we presume that this clump was a behavioral mechanism to prevent desiccation. Petranka (*pers. comm.*) has observed 10–12 *Desmognathus wrighti* in a clump under similar dry conditions, and several species of *Ambystoma* have been reported to exhibit clumping behavior during drought (Petranka, *op cit.*).

PSEUDOEURYCEA GOEBELI (Goebel's False Brook Salamander). **DIET**. Plethodontid salamanders, in particular those in the tribe Bolitoglossini, use ballistic tongue projection to apprehend prey (Deban et al. 1997. Nature 389:27–28). Few data are available on prey size in bolitoglossine salamanders (e.g., Maglia 1996 Copeia 1996:576–586; Bille 2000 Alytes 17:114–124). However, the majority of their diet consists of small arthropods such as Coleoptera and Hymenoptera; large prey items, though rarely taken, are usually long and thin (D. Wake, unpubl. data). In a preserved male *Pseudoeurycea goebeli* in the Museum of Vertebrate Zoology (MVZ 102783; SVL 52.1 mm, head length 12.7 mm, head width 7.9 mm), I found a hymenopteran (*Tiphia*; 10.1 mm x 1.5 mm) and a lepidopteran larva (Arctiidae; 21.7 mm x 5.2 mm) (Fig. 1). The prey items filled the salamander's stomach and body cavity such that the internal organs were pressed flat against the body wall. This record indicates that bolitoglossines are capable of taking larger, heavier prey items than previously thought. Although relatively large items are likely rare in the diet of bolitoglossines, they may be energetically significant (see Greene 1986. Fieldiana Zool. 31:1–12).

I thank E. Richard Hoebeke for identification of the prey items.

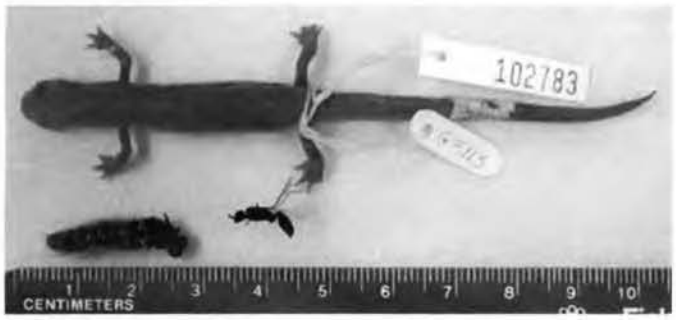

FIG. 1. Adult *Pseudoeurycea goebeli* with two prey items found in the stomach; a larva in the family Arctiidae (bottom left), and the hymenopteran, *Tiphia* (bottom right).

ANURA

ATELOPUS CARBONERENSIS (La Carbonera Harlequin Toad; Sapito Arlequín de La Carbonera). **SURVIVORSHIP**. La Marca and Reinthaler (1991. Herpetol. Rev. 22:125–128.) were the first to report population declines of species in the genus *Atelopus* in Andean Venezuela. The last reported sightings of *A. carbonerensis* were in October 1990 and January 1995 (La Marca and Lötters 1997. Herpetologia Bonnensis 207–213). The species was thought to be extinct, although at one time it was common at the type locality (La Carbonera, Estado Mérida, Venezuela) and surrounding areas (see Barrio 1996. Reptilia 8:26–28; 1998. Acta Biol. Venez. 18[2]:1–93). The decline of *A. carbonerensis* has occurred so drastically in the last decade that Rodríguez and Rojas-Suárez (1999. Libro Rojo de la Fauna Venezolana. 2nd edición. PROVITA, Fundación Polar. Caracas, Venezuela. 472 pp.) listed the species as "Critical Danger," the highest category of endangerment for the Venezuelan fauna. However, on 13 August 1998 at 1500 h, Nancy Chacín, Richard Gavidia, and Carlos Dávila observed and photographed a healthy adult *A. carbonerensis* in the vicinity of "Páramo El Tambor" (8°41'N, 71°12'W), Miraflores hamlet, Mérida state, very close to the type locality. The toad was found above a fallen *Cyathea* tree fern "trunk" within the cloud forest environment (ca. 2200 m elev.). Although *A. carbonerensis* and other harlequin toads in Venezuela and throughout many neotropical realms appear to have declined, we suggest additional survey efforts are needed in localities near historical sites of each species.

Submitted by **DENIS A. TORRES** and **CÉSAR L. BARRIO** Fundación AndígenA, Apartado Postal 210, Mérida 5101-A, Estado Mérida, Venezuela; e-mail: andigena@usa.net (DAT) and cesarlba@yahoo.com (CLB).

BUFO BOREAS (Boreal Toad). **PHORETIC HOST**. On 27 June 2000, we conducted a survey for *Bufo boreas* at a known breeding site in Sayre's Gulch, Chaffee County, Colorado, USA. From the edge of the main breeding pond, we observed several *B. boreas* tadpoles in shallow water, a small number of which were thrashing violently. Upon closer observation, we noted that leeches were attached to the thrashing tadpoles, and after a short time the vigorous movement dislodged the leeches. We selected a 0.5 x 0.5 m area containing about 200 tadpoles and observed them for 20 minutes. During this time, five tadpoles were attacked by leeches, with four attacks directed onto the ventral surface of the tadpole's body and one onto the tail. Once attacked, tadpoles required a mean time of 66 ± S.E. 35 s (N = 5; range 21–107 s) to remove the leeches. We collected samples of these leeches as well as a leech on one of the adult toads. The total lengths of four leeches fixed on slides ranged from 6 to 9 mm (University of Colorado Museum UCM 2394). These were identified as immature *Erpobdella punctata* (Hirudinea: Erpobdelllidae). This leech is distributed throughout North America (Herrmann 1970. Amer. Midl. Nat. 83:1–37). In South Carolina, this leech has been reported to use *Ambystoma maculatum* as a phoretic host (Khan and Frick 1997. J. Nat. Hist. 31:157–161). To our knowledge, this is the first report of this leech attempting to attach to tadpoles or attaching to adult *B. boreas*.

At a site along Pole Creek, Summit County, Colorado, a *Helobdella stagnalis* (Hirudinea: Glossiphoniidae) was attached to an adult male *B. boreas*. This leech occurs through much of Colorado (Hermann, *op.cit.*). While the previous species is non-predatory, *H. stagnalis* probably was feeding on the toad. Leeches have been mentioned as parasitizing metamorphosed *B. boreas* (Hammerson 1999. Amphibians and Reptiles in Colorado. University Press of Colorado, Niwot, Colorado), but their specific identities were not noted.

Funding for this work was provided by Great Outdoors Colorado, the Colorado Division of Wildlife, and the USDA Forest Service. We thank Shi-Kuei Wu (University of Colorado Museum) for identifying the leeches and commenting on this note.

BUFO MARINUS (Giant Toad). **ASSOCIATION WITH OSCARS** (*Astronotus oscellatus*). Ecologists have long been concerned about the negative impacts that some non-native species have on native ecosystems. Many urban and island ecosystems are now largely composed of anthropogenically-assembled communities, with a large diversity of species either intentionally or unintentionally introduced from a variety of regions of the world (Bright 1998. Life Out of Bounds: Bioinvasion in a Borderless World. World Watch Institute, New York. 287 pp.; Mooney and Hobbs 2000. Invasive Species in a Changing World. Island Press, Washington, D.C. 457 pp.; Ota 1993.). Despite the increasingly high profile of invasive alien species (National Invasive Species Management Plan 2000; Invasive Species Executive Order 1998), few studies have been conducted on the evolving relationships among "fortuitously sympatric" vertebrates.

The flora and fauna in Honolulu, Hawaii comprise an assembly of species from many continents (Cox 1999. Alien Species in North America and Hawaii. Island Press, Washington, D.C. 387 pp.; Oliver and Shaw 1953. Zoologica 38:65–95). Between 7 and 10 June 1999, I observed the relationship between an aggregation of ca. 2000 *Bufo marinus* tadpoles and 3 adult oscars (*Astronotus oscellatus*; ca. 40 cm TL; gender unknown) in a large pond (22 x 4 m; 10–50 cm deep, average depth 30 cm) of the East-West Center's ornamental aquatic gardens in Honolulu, Hawaii.

Over the four-day period, I observed the tadpoles and fish for ca. 2.6 h (1030–1040 h and 1245–1315 h each day) and make two "spot checks" (quick look to determine their location only) at different times each afternoon. During all observations, the three oscars swam immediately alongside or above the foraging aggregation of tadpoles. As the tadpoles moved throughout the pond, the aggregation continuously divided and remerged into 1–4 closely associated clusters. When the tadpoles were in a single aggregation, all of the oscars remained with the cluster. If the tadpoles broke into two or three closely associated clusters, the oscars each occupied a cluster. In the one instance that the tadpoles were in four clusters, two oscars each occupied a cluster and the third oscar continuously swam between the other two clusters (ca. 0.5 m apart).

It was not apparent whether the oscars derived any benefit from the close association with the tadpoles. The oscars fed on mosquito fish and juvenile *Tilapia*, but not the tadpoles. *Bufo marinus* tadpoles are known to be unpalatable to predatory fish (Azevedo-Ramos and Magnusson 1999. Copeia 1999:58–67; Crossland and Alford 1998. Aust. J. Ecol. 23:129–137; Lawler and Hero 1997. Wildl. Res. 24:327–334). On the three occasions that tadpoles were engulfed when an oscar ate a fish, the tadpole was immediately released, apparently unharmed. The tadpoles did not appear to be attracting or scaring up prey for the oscars. On one occasion a tadpole was observed to "clean" the sides of an oscar for ca. 30 sec.

This may be a case of mistaken identity. Cichlids (including oscars) are well-studied ethologically (Beeching 1997. Behav. Processes 39:85–93), and unlike most other fish families, cichlids care for their eggs, larvae, and young (McKaye and McKaye 1997. Evolution 31:674–681), which form aggregations (Keenleyside 1991. Cichlid Fishes: Behavior, Ecology and Evolution. Kluwer Academic Publishers, New York).

Many cichlids are known to adopt conspecific or heterospecific young, with seemingly incidental benefits to the parents (Nelson and Elwood 1997. Am. Behav. 54:803–809; Ochi and Yanagisawa 1996. Env. Bio. Fishes 45:141–149; McKaye 1985. Oecologica 66:358–363). The mechanical similarities between tadpoles and many fish species are very strong (McDiarmid and Altig 1999. Tadpoles: The Biology of Anuran Larvae. University of Chicago Press, Chicago, Illinois). Perhaps the aggregation behavior of the tadpoles (Mares 1972. Texas J. Sci. 23:433–435; McDiarmid and Altig, *op.cit.*), triggered a guarding response in the oscars (Keenleyside, *op. cit.*). The oscars were frequently aggressive (charging, gaping, biting) toward one another, as well as koi and adult *Tilapia*. Given that the tadpoles are unlikely to be palatable to other fish in the pond, the oscars probably did no harm but also provided no advantage to the tadpoles.

Submitted by **JAMIE KRISTINE REASER**, U.S. Invasive Species Council, 1951 Constitution Ave, NW, Suite 320, South Interior Building, Washington, D.C. 20240, USA (e-mail: jamie_reaser@doi.gov) and **WENDY FOX KNIGHT**, Center for Conservation Biology, Department of Biological Sciences, Stanford University, Stanford, California. 94305, USA (e-mail: wfox@leland.stanford.edu).

ELEUTHERODACTYLUS ABBOTTI (NCN). **PATTERN POLYMORPHISM**. Species in the genus *Eleutherodactylus* are frequently polymorphic (Savage and Emerson 1970. Copeia

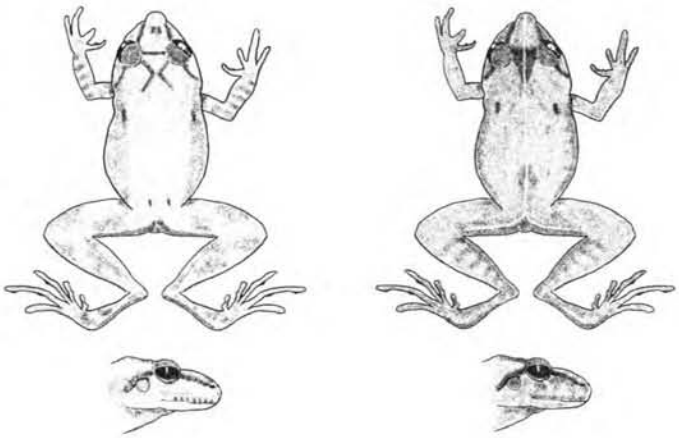

FIG. 1. Pattern polymorphism in *Eleutherodactylus abbotti* from the eastern Sierra de Baoruco, Dominican Republic. Drawings are composites of numerous specimens for the purpose of representing variable pattern elements in four geographically proximate localities (Table 1). The specimen on the left illustrates a dorsal pattern with contrasting sides; narrow, hourglass-shaped interocular bar with corresponding ridge pattern; distinct eyeline and tympanic stripe; headpatch restricted to frons; banded arm pattern; mottled leg pattern; distinct side and sacral spots, the latter confined to ridges; dark arch mark; banded lip line; and lack of a middorsal stripe. The specimen on the right illustrates a uniformly dark dorsal pattern; wide, filled interocular bar; distinct eyeline and tympanic stripe; uniform arm pattern; banded leg pattern; distinct side spots; scapular spots not confined to ridges; ridges scattered; lip line mottled; and narrow middorsal stripe extending onto thighs.

TABLE 1. Pattern polymorphism in *Eleutherodactylus abbotti* from the eastern Sierra de Baoruco, Dominican Republic. Population 1 consisted of four localities on the northeastern slope above the city of Barahona (elev. 300–450 m); population 2 of three localities on the northern slope above the town of Cabral (700–850 m); population 3 of two localities on the southeastern slope above the town of Enriquillo (250–380 m); and population 4 of five localities on an eastern ridge (Loma Remigio; 1050-1150 m). The first three populations are in moist upland rainforests and the fourth in cloud forest. However, all sites have been severely altered by human activity. Asterisks (*) indicate traits for which counts differed significantly from expected Hardy-Weinberg frequencies (Contingency tests; _ = 0.05); note that we tested only traits for which three phenotypes exist. Crosses (†) designate traits for which interpopulational differences cannot be explained by chance.

1970:623–644). The two most common species in the Sierra de Baoruco, Dominican Republic, are *E. abbotti* and *E. armstrongi* (Howard et al. 1997. Herpetol. Nat. Hist. 5:77–82). Dorsal color of the latter ranges from "brown or tan to clear yellow, orange, orange-red, or yellow-green" (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville), but an examination of over 200 specimens revealed very little variation in pattern. In contrast, *E. abbotti*, despite a broader distribution throughout both the North and South paleoislands of Hispaniola, is considerably less variable in color, ranging from "grayish green to tan, rarely reddish tan to brown" (Schwartz and Henderson, *op. cit.*). However, both Cochran (1941. Bull. U.S. Natl. Mus. [177]:398 pp.) and Schwartz (1977. Cat. Amer. Amphib. Rept. 191.1-191.2) commented on the variability of the dorsal pattern. An examination of 18 pattern elements of 155 frogs from four geographically proximate populations in the eastern Sierra de Baoruco revealed considerable variation both within and between populations (Table 1, Fig. 1). Only the tympanic stripe was consistently present and distinct. This character is diagnostic of these populations.

José Ottenwalder, United Nations Development Programme, facilitated our work in the Dominican Republic. Gloria Santana, Departamento de Vida Silvestre, and Katarzyna Grasela, Dirección Nacional de Parques, graciously issued permits. Linda Trueb and John S. Simmons, University of Kansas Natural History Museum, provided access to specimens. Fieldwork was funded by a National Science Foundation grant (DBI-9732257) awarded to RP.

YESKA**, Department of Biology, Wayne State College, Wayne, Nebraska 68787, USA, and **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA; e-mail (RP): powellr@mail.avila.edu.

ELEUTHERODACTYLUS COCHRANAE (Coquí Pitito). **REPRODUCTION**. We report observations of two *Eleutherodactylus cochranae* nests. On 22 July 1996, we found a double egg clutch in a bromeliad leaf, 30 cm above ground, in a patch of ground bromeliads located at the University of Puerto Rico, Río Piedras Campus. This double clutch had no attending adult at the time it was found. One clutch had five eggs in an intermediate stage of development. The second clutch had four recently hatched individuals, (mean SVL 7.1 mm; SD 0.21, range 6.9–7.3), and two eggs in an advanced stage of development. The diameter of one of these eggs was 6.2 mm and both embryos had a bifid egg tooth. The double clutch was deposited in the Museo de Biología, Universidad de Puerto Rico-Recinto de Río Piedras (UPRRP–5750). On 20 February 1998, we found another clutch in the same area that was attended by an adult male (SVL ca. 20 mm) brooding the eggs. This clutch was laid in a folded bromeliad leaf, that together with the leaf above it, provided cover and protection by enclosing both the egg clutch and the attending adult. The egg clutch had seven eggs, all together in two parallel rows. The adult was brooding the eggs. Two days later, the clutch hatched and the adult stayed with the juveniles for 4–5 days. Eight days after hatching, the juveniles were not found and presumably had dispersed. Because egg clutches were found in February, July, and October, and gravid females were observed in March, September, and October we think that *Eleutherodactylus cochranae* breeds all year around (Joglar 1998. Los Coquíes de Puerto Rico: Su Historia Natural y Conservación. Editorial de la Universidad de Puerto Rico. San Juan. 232 pp.). We are grateful to Neftalí Ríos, Vilmarie Rentas, Loema Jaramillo and Jorge Billoch for their assistance in the field.

HYLA CINEREA (Green Treefrog). **PRE-HIBERNATION LIVE BODY WEIGHT**. Little is known about the live body mass of Arkansas green treefrogs prior to hibernation. These frogs require fat stores to survive winter hibernation. Hibernation appears to occur from the last week in October through mid-March/early April depending upon fluctuations in seasonal weather patterns (unpubl. data). These data may be important for comparisons to other regions with different length hibernation periods as well as for comparisons to other habitat types. On 14 October 2000 we collected 198 *Hyla cinerea* by spotlighting vegetation between 2300 and 2330 h along agricultural ditches. The site was located ca. 6.4 km S Jonesboro on St. Hwy. 1, Craighead County, Arkansas, USA. Specimens were collected by hand and stored in an ice chest over night. The next day living specimens were weighed with an electronic analytical balance to the nearest 0.01 g. The mean prehibernation body mass was 1.95 g, SD = 0.7277. The maximum body mass was 4.69 g and the minimum observed body mass was 0.58 g. Fifty percent of specimens weighed more than 1.82 g, 75% weighed more than 1.43 g, and only 25% weighed more than 2.32 g. The 95% confidence interval was between 0.75 g and 3.37 g. Body lengths were not recorded for these individuals because the specimens were to be used in other studies, and we desired to minimize the stress experienced by the animals.

NYCTIBATRACHUS MAJOR (Large Wrinkled Frog). **FOOD HABITS.** *Nyctibatrachus major* is an aquatic, stream-dwelling ranid endemic to southwestern Ghats of India. Although information on occurrence, habitat features, larval morphology, and femoral glands are available (Daniels 1997. Cobra 28:1–14; Krishnamurthy et al. 1992. J. Indian Inst. Sci. 72:385–393; Krishnamurthy 1997. Froglog 20:2; Pillai 1978. Bull. Zool. Surv. India 1:135–140), there is no information available on the food habits of this species. This is the first note on the food habits, especially predation of *N. major* on sympatric ranids.

During an amphibian survey in Kudremukh National Park of Western Ghats on 22 May 1998, the predation of *N. major* on an aquatic frog was noted. This stimulated us to examine the food habits of this species. Stomach contents of 48 adult and 8 subadult *N. major* (mean SVL = 34.18 mm, SD = 16.25 mm, range = 13–54 mm; mean mass = 7.86 g, SD = 6.12 g, range = 2–26.7 g) were examined from 14 different localities. Thirty-one adults contained partly-digested subadult *Limnonectus limnocharis, Rana cyanophlyctis,* and adult *Micrixalus saxicola*. Among the remaining specimens examined, insect larvae predominated: *Ophiogomphus* sp. (Gomphidae), *Psephenus* sp. (Psephenidae), *Enochrus* sp. (Hydraenidae), *Neides* sp. (Neididae), *Sminthurinus* sp. (Sminthuridae), and members of Dytiscidae and Haliplidae. Organic debris was noted in some cases and in two adults and six subadults the stomachs were empty.

Analysis of amphibian diversity at all 14 localities revealed the following frogs sympatric with *N. major*: *L. limnocharis, M. saxicola, R. brevipalmata, R. temporalis, R. semipalmata, R. cyanophlyctis, Tomopterna rufescens, Microhyla rubra, M. ornata, Philautus sp.* and *N. pygmaeus*. Among these, *R. cyanophlyctis, R. temporalis, L. limnocharis,* and *M. saxicola* represented 50, 40, 30, and 20% of the total observations. Among these species, *R. cyanophlyctis, L. limnocharis,* and *M. saxicola* were confined to the microhabitat of *N. major*, while *R. temporalis* was confined to the litter mats at the periphery of the microhabitat. Hence, the high degree of predation by *N. major* on *R. cyanophlyctis* and *L. limnocharis* could be related to the microsympatry of these species and the selective feeding of *N. major*.

We thank Charles W. Painter for his valuable suggestions on this manuscript.

RANA AURORA DRAYTONII (California Red-Legged Frog). **PREDATION**. Although the introduced bullfrog (*Rana catesbeiana*) has long been suspected as a predator of the federally threatened California red-legged frog (*R. aurora draytonii*)

[e.g., see Moyle 1973. Copeia 1973:18–22], there have been no published field observations to support this contention. Since the bullfrog is now widely established within the historical range of the California red-legged frog, it is important to determine the degree of threat presented by this introduced predator. We therefore provide the first documented evidence of adult bullfrogs feeding on larval and juvenile California red-legged frogs in the wild.

On 10 July 1996, a pair of 104 mm and 113 mm SUL adult bullfrogs were collected ca. 2200 h from "Detjen Pond," located ca. 1 km SE of Livermore, Alameda County, California, USA. These bullfrogs were among 156 others removed over a 1.5-yr period from the permanent 0.3-ha pond that also contained dozens of California red-legged frogs of all sizes. Both bullfrog specimens contained a juvenile (28 and 30 mm SUL) California red-legged frog. The only other prey item found was one giant water bug (Belostomatidae). The bullfrogs and their stomach contents have been deposited in the herpetology collection of the California Academy of Sciences (CAS 204240–242).

On 8 and 11 July 1997 at Ledson Marsh, Annadel State Park, Sonoma County, California, three larval California red-legged frogs (Gosner stage 37–39) were flushed from the stomachs of two adult female bullfrogs (180 and 185 mm SUL). Although the skin of the tadpoles had largely been digested, species determination was based on concurrent live-trapping of red-legged frog larvae of the same size and development stage (bullfrog tadpoles at Gosner stage 37 were not found in the marsh until the middle of August). A single larval Pacific treefrog (*Hyla regilla*) was also recovered. Ledson Marsh is an 11-ha ephemeral wetland that has reproducing populations of at least 127 adult California red-legged frogs and 27 adult bullfrogs (Cook 1997. Microhabitat Use and Reproductive Success of the California Red-legged Frog [*Rana aurora draytonii*] and Bullfrog [*Rana catesbeiana*] in an Ephemeral Marsh. Unpubl. M.A. Thesis, Sonoma St. Univ., Ronhert Park, California).

It is well known that bullfrogs feed on a wide variety of anurans including conspecifics (Bury and Whelan 1984. U.S. Fish Wildl. Serv., Res. Publ. [155]:1–23). More recently, bullfrogs have been documented to eat larval and juvenile northern red-legged frogs (*R. a. aurora*) in the field (Twedt 1993. A Comparative Ecology of *Rana aurora* Baird and Girard and *Rana catesbeiana* Shaw at Freshwater Lagoon, Humboldt County, California. Unpubl. M.A. Thesis, Humboldt St. Univ., Arcata, California) and under experimental conditions (Kiesecker and Blaustein 1995. The Wildl. Soc. Second Ann. Conf. Abstracts, Portland, Oregon). Our observations indicate that adult bullfrogs will also readily eat larval and juvenile California red-legged frogs when the two species come into contact. Therefore, resource managers should continue their efforts to limit the spread of bullfrogs into remaining red-legged frog habitats.

Our thanks to David Muth for information about Detjen Pond, and to Marc P. Hayes, Galen B. Rathbun, and Norman J. Scott, Jr. for reviewing the manuscript. Permission to handle and collect specimens was granted under U.S. Fish and Wildlife Service and California Department of Fish and Game permits issued to the authors.

RANA PALUSTRIS (Pickerel Frog). **PRODUCTION OF ODOR**. Odor production has been reported in at least three species of North American ranids, *Rana septentrionalis* (Harding 1997. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press, Ann Arbor 378 pp.), *R. capito* (Richter, pers. comm.), and *R. muscosa* (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Company, Boston, Massachusetts. 336 pp.). To my knowledge, odor production has not been reported in the pickerel frog, *R. palustris*. During July 2000, I collected three adult pickerel frogs along a road in Shindagin Hollow State Forest, Tompkins County, New York, USA (42°18'N, 76°18'W). As the first frog was handled, it began to emit a distinctive odor that was likened to that of alfalfa sprouts or the inside of a latex glove. All three frogs eventually produced the odor while being handled in the field. This odor is distinctly different from that of mink frogs. I was able to induce the production of this odor repeatedly in the laboratory, by handling or with an electrostimulation device. The pickerel frog's distasteful secretions protect it from attack by the shrew, *Blarina brevicauda* (Formanowicz and Brodie 1979. Amer. Midl. Nat. 101:456–457). The odor was noticeable, but not overtly aversive to humans. Given the noxious nature of pickerel frog secretions, I suggest that this odor is an olfactory aposematic cue.

RANA SEPTENTRIONALIS (Mink Frog). **LARVAL PREDATION**. Heeden (1970. The Ecology and Life History of the Mink Frog, *Rana septentrionalis*, Baird. PhD Diss., Univ. Minnesota. 129 pp.) reviewed those vertebrates reported as predators of mink frog tadpoles. Among birds, he listed only the great blue heron (*Herodia ardeas*) and other Ciconiformes, and speculated that the belted kingfisher (*Megaceryle alcyon*) might also take mink frog tadpoles. Although Mallory and Larivière (1998. Canadian Field-Nat. 112:714-715) reported 4.5 cm mink frogs in the diet of the wood duck (*Aix sponsa*), there seems to be no report of mink frog tadpoles in the diet of North American waterfowl known to prey on vertebrates, specifically the hooded merganser (*Lophodytes cucullatus*). Bent (1923. US Nat. Mus. Bull 126) and Johnsgard (1978. Ducks, Geese, and Swans of the World. Univ. Nebraska Press, Lincoln) listed tadpoles (species unidentified) as items in the hooded merganser diet without citing references. Bellrose (1978. Ducks, Geese, and Swans of North America. Stackpole Books. Pennsylvania) stated that the diet of the hooded merganser is poorly known and reviewed seven feeding studies for this species, none of which listed tadpoles in this ducks diet.

Here we document two hooded mergansers feeding on mink frog tadpoles. On 2 October 1995, local hunter Mark Cougle shot two immature hooded mergansers (1 male, 1 female) while the

birds were feeding on Belvidere Lake, Kings County, New Brunswick, Canada (45°17'N, 66°17'W). During preparation of the birds for addition to the New Brunswick Museum (NBM), three Gosner stage 40 *Rana septentrionalis* tadpoles were taken from the esophagus of these birds (Gosner 1960. Herpetologica 16:183–190). The stomachs were empty. Total lengths for two of the tadpoles were 98 and 101 mm. Although all tadpoles had been swallowed intact, decomposition prevented measurement of one. Identification of tadpoles was based on comparison with collections in the New Brunswick Museum. Tadpoles taken from the hooded mergansers have been retained among stomach samples in the bird collection of the New Brunswick Museum (NBM 9913; NBM 9917).

RANA TEMPORARIA (European Common Frog). **DIET**. The European common frog is widespread, and although many aspects of its biology have been studied, very little is known about most northern populations. Stomach contents of 21 *Rana temporaria* (SVL 23–66.4 mm) collected July 1999 from Kandalakscha Bay (White Sea; Russia; 66°17'N, 33°40'E) were examined. Other population characteristics were reported by Borczyk and Malak (2000. *In* Zamachowski (ed.), Biology of Amphibians and Reptiles, pp. 13–15. WSP Kraków). Table 1 summarizes data collected during this study.

TABLE 1. Stomach contents of 21 *Rana temporaria* from Kandalakscha Bay.

TESTUDINES

CHRYSEMYS PICTA (Painted Turtle). **TRAPPING**. Hoop traps and basking traps have long been used to capture turtles. Papers on turtle trapping are usually examinations or modifications of one type of trap (Cagle 1950. Ecol. Monogr. 20:31–54; Frazer et al. 1990. Copeia 1990:1150–1152). Thomas et al. (1999. J. Herpetol. 33:511–515) used differential hoop and basking trap success to evaluate seasonal patterns of behavior in the red-eared slider (*Trachemys scripta*). Otherwise, I know of no study that compares the efficiency of the two types of traps. This note makes such a comparision, using data from painted turtles (*Chrysemys picta*).

Two three-ring hoop traps (91 cm diam, 2.5 cm mesh) and one five-ring hoop trap (61 cm diam, 2.5 cm mesh) were placed in a pond at the University of Toledo's Stranahan Arboretum (Sylvania Township, Ohio, USA) from 26 May to 30 June 1999. Traps were anchored and partially submerged in areas where large populations of painted turtles were seen basking and foraging. Traps were baited with salmon heads and checked daily. Bait was replaced as needed, usually every other day, to prevent rotting. The area where the traps were set was not disturbed, other than the daily check. After five weeks, two snapping turtles (*Chelydra serpentina*) had been caught. The bait was intact in all the traps, except those that caught the snapping turtles, suggesting that no painted turtles entered the traps and subsequently escaped. On 9 June 1999, two weeks after the hoop traps were set, two basking traps were placed in the same pond, in the same area as the hoop traps. The basking traps were constructed from four pieces of 5.12 cm diam PVC pipe glued with plumber's compound. Extending out at angles from the sides was chicken wire (2.5 cm mesh). The wire was attached to the sides at the bottom with a series of cable ties to form a basket. The unbaited basking traps were checked daily. In 21 days of trapping with basking traps, I recorded 54 captures of 46 individual painted turtles, a rate of ca. 2.6 captures per day. Captured turtles represented all age cohorts, including hatchlings, and an almost equal sex ratio. This suggests that, unlike hoop traps, the presence of one sex does not increase or decrease the likelihood of trapping the other sex (Frazer et al., *op. cit.*), nor does the presence of a large turtle seem to deter a small turtle from being captured.

Chysemys picta were more readily captured in this pond using basking traps rather than hoop traps. Additional benefits of the basking traps include the wide range of sizes and sexes captured, the low cost (less than US $5/trap), and ease of deployment.

I thank the University of Toledo's Stranahan Arboretum, Sandra Stutzenstein, and Elliot Tramer for their support.

ERECTMOCHELYS IMBRICATA (Hawksbill Turtle). **NESTING.** Adult hawksbill turtles have been sighted in the waters of the southern islands of Singapore (Ng and Wee 1994. The Singapore Red Data Book. The Nature Society Singapore, 343 pp.). However, records of turtle nesting on the island are scarce.

Here we report the first record of nesting by a hawksbill turtle on the rocky shore at Labrador Beach Park (01°17.7'N, 103°45'E), Singapore, the last beach-cum reef left in this island republic (Lim et al. 1995. Rhythms of the Sea: The Life and Times of Labrador Beach, Nanyang Technological University & National University of Singapore. 165 pp.).

On 20 July 1999, a hawksbill turtle was observed emerging from the sea, fronting the rocky shore during mid-high tide (1.0 m, Year 2000 Singapore Tide Table & Port Information, Marine and Port Authority of Singapore. 220 pp.) at 2300 h, an hour before moonrise. The turtle crawled up the beach to where the base of the hill meets the shoreline and a concrete embankment. Unable to move further up the shore, the turtle proceeded to dig a shallow pit and laid its eggs. The beach substrate at the nest site was pebbly and sandy; the shore with large protruding boulders is inundated by tidal waters at high tide up to the base of the precipitous sea-facing wall of the hill.

The eggs in the nest were examined three days later on 23 July 1999 to assess their condition. The eggs were creamy in color and their shells were depressed. None of the eggs had a chalky white spot on the shell. A white spot appears on marine turtle eggs soon after eggs are laid, and its progressive development over the eggshell is indicative of embryonic development. Only viable eggs develop a white spot (Chan 1989. Copeia 1989:42–47; Diong et al. 1999. Sarawak Mus. J. 54:301–308). Two eggs were dissected but failed to show any sign of embryonic development. The eggs appeared to have drowned. The nesting site at the base of a precipitous sea-facing wall is subjected to flooding during high tides. We abandoned a plan to fence the nest for *in situ* incubation. Instead, the eggs were transferred into a Styrofoam box containing sand moistened with artificial seawater.

Nest depth (to top of egg chamber) was 27 cm, and 56 cm to bottom of chamber. Clutch size was 99 eggs. A sample of 22 eggs were measured (Mitutoyo calipers) and weighed (Ohaus) on site. Eggs averaged 34.44 ± 0.62 mm (range: 33.50–36.60 mm) in diameter and 23.56 ± 0.86 g (22–24 g) in weight. The styrofoam box with eggs was transferred to a laboratory incubator at 30°C to assess, as a precautionary measure, if there was further development in any of the eggs. Eggs examined a week later showed no external signs of embryonic development. Five eggs were dissected but had no signs of life.

This nesting record is important for Singapore whose original coastline with natural sandy beaches, mangroves, and coral reefs has been either altered or destroyed through massive land reclamation for housing, port, and infrastructure development. Designated as a nature reserve in 1951 but downgraded to a nature park in 1973, Labrador Beach Park including the parkland and rocky shore where the nesting occurred, has reason now to be redesignated as a nature reserve.

We thank Ian Turner and Cheryl Lim of the National Parks Board, Singapore for field assistance. Eggs are deposited at Zoological Reference Collection (ZRC.2.4761), Department of Biological Science, National University of Singapore. Fred H. C. Chua, Senior Curator, Underwater World Aquarium Pte. Ltd., Singapore, verified color photographs of the turtle. Photographs of nesting and video recording of nest excavation are deposited at National Parks Board, Singapore.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **USE OF ABANDONED BURROWS BY JUVENILES**. During July 1999, a number of juvenile gopher tortoises were excavated from supposedly "abandoned" adult burrows found on two different tortoise relocation sites located on the Brooksville Ridge, Citrus County, Florida, USA. The Florida Fish and Wildlife Conservation Commission's (FFWCC) current definition of an abandoned burrow is based on the statement made in Auffenberg and Franz (1982. *In* Bury [ed.], North American Tortoises: Conservation and Ecology, pp.95–126. U.S. Fish and Wildlife Service, Wildl. Res. Rep. 12) describing an "old" burrow as one in which the mouth has been washed in or covered with debris. All the "abandoned" burrows we excavated on these sites did match the description of appearing "washed in or covered with leaves" and had no outer indications of habitation by tortoises. However, we put a number of small twigs across the mouths of some of these burrows where the floor still appeared to be somewhat flat. Subsequent checks of these twigs indicated that something had gone into some of these burrows. Using a flashlight to carefully scrutinize the burrow floor beyond the mouth, tracks of tortoises could be seen in three of the burrows. Therefore, we decided to excavate these supposedly abandoned burrows. These burrows ranged from 200 mm to 290 mm in horizontal width indicating that they were made by and at one time used by adult tortoises.

All burrows on the sites were excavated using a backhoe. On the first site, a total of 11 "abandoned" burrows were excavated and 3 (27%) contained juvenile tortoises ranging in carapace length from 84 mm to 154 mm. The mean burrow length at the first site was 9.2 m with a vertical depth of 2.8 m. On the second site, 18 "abandoned" burrows were excavated, with 3 (17%) of the burrows containing juvenile tortoises with a carapace length ranging from 86 mm to 141 mm. The mean burrow length at the second site was 8.7 m with a vertical depth of 2.4 m.

The number of juvenile tortoises found on each site (3 each) compared to the number of juvenile-sized burrows indicates that perhaps abandoned burrows may play a significant role in providing shelter for tortoises from juvenile through the subadult size classes. This is further indicated in our four-year survey of burrows and tortoises on the Institute's 100-acre preserve (also on the Brooksville Ridge) where we have collected and marked 17 juvenile tortoises (less than 180 mm CL) yet we have only been able to locate 5 appropriately-sized burrows in five semi-annual burrow surveys, including two which have been conducted immediately after summer burns. Under the current FFWCC definition, the 29 burrows of which 6 contained juvenile tortoises would all have been considered abandoned and would not have been excavated. Based on these preliminary findings, we believe that the definition of an abandoned burrow should be redefined as a burrow that has lost its "half moon shape" becoming circular or very irregular in shape with rooted vegetation (live or dead) occurring at or near the base of the burrow mouth.

SERPENTES

GRASSLAND SNAKES. DIET. Although dietary habits of North American snakes have been relatively well documented during the last 50 years, little information exists on the diet of snakes inhabiting grasslands or prairies (Cavitt 2000. Herpetol. Rev. 31:47–48). Two of the three species encountered during our study, the common garter snake (*Thamnophis sirtalis sirtalis*) and blue racer (*Coluber constrictor foxii*), are known opportunists and diet is influenced by prey availability (Smith 1961. Bull. Illinois Nat. Hist. Surv. 28:1–298). Therefore, dietary studies carried out in different habitat types may be insufficient for comparison to one another.

We collected diet-related data at Prairie Ridge State Natural Area (PRSNA) in Jasper County, Illinois, USA. PRSNA is a 640 ha restored grassland maintained by the Illinois Department of Natural Resources. Predation events were recorded for snakes encountered during an avian nest study during the months of August through July 1996 to 2000. In addition, 276 snakes were captured in 2000. Of these, 4.3% produced dietary results from stomach contents. Snakes were captured by walking transects (2.0 m wide) and by the use of cover boards (0.6 m x 2.0 m sheets of corrugated metal barn roofing) to attract snakes. Total length (TL), snout-vent length (SVL), weight after regurgitation (WT), head width (HW), and gape to the nearest mm or g, were taken at the time of capture. Gape was measured by fully extending the mandibular-maxillary joint between 140 and 160 degrees with calipers. All snakes were forced to regurgitate regardless of stomach distension, using techniques explained by Fitch (1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 156–157. Macmillan Publishing Co. New York). Prey items were identified in the field and fed back to the animal. Individuals were scale-clipped for future identification and released at point of capture.

During the five years of field observation, 10 predatory events were recorded for three species of snakes. The majority of these events (67%) involved passerine eggs, nestlings, and fledglings, while small mammals made up 22% of the events. At no time did we witness snakes preying upon invertebrates. In 2000, 276 snakes captured along transects and under panels produced 14 regurgitated samples (Table 1). The majority (50%) of stomach contents were small mammals, and 31% were invertebrates. Only one event was noted for *C. constrictor*.

The *T. sirtalis* at our site appeared to be opportunistic feeders with a diet consisting of 47.4% avian, 31.6% mammal, and 26.3% invertebrate (events are listed as >100% because one stomach contained prey from two of the above classes). Our results differ from diet studies compiled by Ernst and Barbour (1989. Snakes of East-

TABLE 1. Prey items of three grassland snake species as noted from predation events or stomach contents at Prairie Ridge State Natural Area in Jasper County, Illinois, USA. An * indicates a witnessed predatory event. All other records are from stomach contents.

Predator	TL (mm)	SVL (mm)	WT (g)	Gape (mm)	HW (mm)	Prey items

	969	—	474	—	—	One unidentified small mammal adult
C. constrictor	1305	1018	—	47	21	* One *Thamnophis sirtalis*

ern North America. George Mason Univ. Press, Fairfax, Virginia. 282 pp.) who demonstrated that amphibians and earthworms were the important foods consumed by adults and juveniles (35–90%).

All events recorded from this study for the prairie kingsnake (*Lampropeltis calligaster calligaster*) involved small mammals. This is similar to what has been reported by other investigations. Klimstra (1959. Herpetologica 15:1–5) discovered that prairie kingsnake prey items consisted only of small mammals. Likewise, a study by Fitch (1978. Trans. Kansas Acad. Sci. 81:353–363) found that the prairie kingsnake was primarily a mammal eater, with snakes and lizards making up a small percentage of the food. Heske (1999. Illinois Natural History Survey Final Report for FY 99) found moderate to high numbers of small mammals at PRSNA from 1995 to 1999. Therefore we would expect mammals to be a large portion of the diets of *L. calligaster* and *T. sirtalis*.

Body measurements are presented (Table 1) because size of the snake influences the type or quantity of prey taken. Juvenile snakes will have a high percentage of soft-bodied prey items such as invertebrates or amphibians, while adults will readily consume larger vertebrate species (Mushinsky. 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 302–334. Macmillan Publishing Co. New York; See also Tucker 2000. Herpetol. Rev. 31:106–107).

The information presented here is unique in two ways. First our data show a different prey preference for garter snakes found at PRSNA, as compared to the other studies compiled by Ernst and Barbour (*op. cit.*). This information reinforces findings that opportunistic feeders may have a site specific diet (Kephart 1982. Oecologia 52:287–291; Gregory and Nelson 1991. Can. J. Zool. 69:988–994). Second, the percent of witnessed predation events on birds was much higher than the percent of avian items found in stomachs. This may have occurred because items such as eggs and nestlings would pass quickly through the digestive system, or would not have been a discernable part of the diet when using regurgitation. This could lead to an underestimate of avian items consumed when regurgitation is the only method used.

We acknowledge the financial support of the Illinois Council for Food and Agricultural Research (C-FAR), and the Illinois Department of Natural Resources Division of Natural Heritage Small Wildlife Preservation Fund. We thank Eric Kershner and Jeff Walk for field notes on the observations of predation events, prey identification, and review of this manuscript. We also thank field assistant Nisa Tawjareon for many hours of snake collection.

PHILODRYAS OLFERSII (NCN). **COURTSHIP**. Little is known about courtship and mating aggregations of Neotropical snakes. On 23 March 1998 at 1800 h (air temp = 25°C), we observed courtship behavior involving four adult *Philodryas olfersii*. The snakes were observed on a tree branch ca. 5 m above the ground at CISM (Campo de Instruÿão de Santa Maria, RS, south Brazil, 29°43'S, 53°44'W). A female and two males (SVL 910 mm, 700 mm, 760 mm; ZUFSM 1596, 1597, 1598, respectively; Setor de Zoologia, Universidade Federal de Santa Maria) were captured after a few minutes of observation when they tried to flee. The fourth snake escaped.

Before capture, the males alternately rubbed the female and stayed in direct contact with her. During this process, we observed the following behaviors: undulation, dorsal advance, and dorsal body looping. These behaviors are consistent with the Tactile-Chase phase of courtship (Gillingham 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 184–209. Macmillan Publ. Co., New York). No aggressive behaviors or the latter phases of courtship (tactile alignment, intromission, and coitus) were observed. This appears to be the first record of courtship behavior for *P. olfersii* in the field.

We thank Augusto Shinya Abe for comments on this manuscript.

CECHIN**, Departmento de Biologia, Universidade Federal de Santa Maria, Faix Camobi, KM 09, Camobi, Santa Maria, Rio Grande do Sul, Brazil (e-mail: cechinsz@ccne.ufsm.br), and **PAULO AFONSO HARTMANN**, Pós-Graduaÿão em Ciências Biológicas-Zoologia, Instituto de Biociência, Universidade Estadual Paulista, C.P. 199, 13506-900, Rio Claro, São Paulo, Brazil (e-mail: pahart@rc.unesp.br).

THAMNOPHIS EQUES (Mexican Garter Snake) and ***THAMNOPHIS SCALARIS*** (Mexican Alpine Blotched Garter Snake). **PREDATOR/PREY**. On 7 June 1999 (1115 h), we captured a female *Thamnophis eques* (555 mm SVL, 130 mm TL, 70 g). It was under a rock near a pond, surrounded by *Salix* sp., at the Area de Conservación e Investigación Ecológica El Bordo, Las Maravillas (99°41'W, 19°24'N), 17 km NW of Toluca City, México (elevation 2550 m). The snake was palped and regurgitated one fragment (60 mm, 3.0 g) of a partially digested *T. scalaris* (22 ventral scales). On 29 June 1999, we captured a female *T. eques* (570 mm SVL, 150 mm TL, 140 g) and a female *T. scalaris* (430 mm SVL, 110 mm TL, 40 g). The snakes were placed in the same bag, and after two hours the *T. eques* was observed consuming the *T. scalaris*. The *T. scalaris* was being ingested head first, and 1/4 of its body had been swallowed when we checked the bag.

Snakes have not been reported as prey of any species of *Thamnophis* (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, Oklahoma. 327 pp.). In addition, our observation represents the first published record of garter snakes (*T. scalaris*) as natural prey of other garter snakes (*T. eques*). Reptiles reported in the diets of *Thamnophis* include lizards and skinks (Clark 1974. Herpetologica 30:372–379; Drummond and Macias-García 1989. Behaviour 108:23–43; Fouquette and Rossman 1963. Herpetologica 19:185–201; Lemos-Espinal and Ballinger 1992. Herpetol. Rev. 23:117).

CP 50000, Toluca, Estado de México, México (e-mail: sadiel@cibnor.mx).

XENODON NEUWIEDII (Quiriripitá). **DIET.** The colubrid *Xenodon neuwiedii* occurs in central and southern Brazil, Paraguay, and northern Argentina (Peters and Orejas-Miranda 1970. Catalogue of the Neotropical Squamata: Part I. Snakes. Bull. U.S. Nat. Mus. 297:324). This terrestrial, diurnal snake is associated with forested areas and is usually found on the forest floor close to bodies of water (Marques 1998. Composição Faunística, História Natural e Ecologia de Serpentes da Mata Atlântica, na região da Estação Ecológica Juréia-Itatins, São Paulo, SP. Ph.D. dissertation. Instituto de Biociências, Universidade de São Paulo, São Paulo. 135 pp.; Sazima and Haddad 1992. *In* Morellato [ed.], História Natural da Serra do Japi, pp. 212–236. Editora da Unicamp/Fapesp, Campinas). This species is also considered a mimic of *Bothrops jararaca* (Sazima 1992. *In* Campbell and Brodie, Jr. [eds.], Biology of the Pitvipers, pp. 199–216. Selva Publ. Tyler, Texas). It feeds strictly on anurans and mainly on *Bufo* species (Jordão 1996. Estudo Comparativo da Alimentação e da Reprodução de *Waglerophis merremii* e *Xenodon neuwiedii* [Serpentes: Colubridae]. Master's thesis. Instituto de Biociências, Universidade de São Paulo, São Paulo. 93 pp.; Marques, *op. cit.*; Sazima and Haddad, *op. cit.*). Here we report on two hylids from the stomach of one snake found in the wild.

On 29 January 2000, at 1400 h, VXS found an adult male (SVL = 555 mm, tail = 117 mm) moving on the forest floor near a stream at the Estação Biológica de Boracéia, Salesópolis, São Paulo, Brazil (23°38'S, 45°52'W, 900 m elevation). Upon capture it regurgitated two relatively small *Hyla hylax* (Hylidae). The snake and its stomach contents will be deposited at the Museu de Zoologia da Universidade de São Paulo (MZUSP), in São Paulo. Estimated prey/predator mass ratio was 0.04 and 0.06 for each prey item. Estimated prey/predator mass ratios reported for this snake varied from 0.003 to 0.4 (N = 27) (Jordão, *op. cit.*). Individual snakes containing two prey items have been reported four times in the Instituto Butantan collection (IB 41051, 56486, 56491, and 56497; Jordão, *op. cit.*). However, hylids are rare in the diet of this species.

We thank MZUSP for permission and support to study at the Estação Biológica de Boracéia (EBB) and Jaime Bertoluci for comments and suggestions on this manuscript.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 32, Number 1 (March, 2001).

CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander). USA: WISCONSIN: Jackson Co: Green Bay and Western RR right-of-way, within 100 m (west) of Bartell Road and ca. 100 m north of Minnesota Rt. 54, west of City Point (Sec. 34, T22N, R1E). 29 May 2001. Philip A. Cochran, with Andrew G. Cochran. MPM 33144. Verified by Gary Casper. First documented record from the county (Casper 1996, Geographic Distribution of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Museum, Milwaukee).

Submitted by **PHILIP A. COCHRAN** and **ANDREW G. COCHRAN**, Biology Department, Saint Mary's University, Winona, Minnesota 55987, USA.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: SOUTH CAROLINA: McCormick Co: Clarks Hill, South Carolina Army National Guard Training Site (SCANGTS) (33°47'16"N, 82°16'52"W). 23 May 2000. T. M. Floyd and E. S. Kilpatrick. Clemson University (CUSC 2079). Verified by Stanley Miller. New county record. Known from localities in the northern Piedmont; first record within the Piedmont from the Savannah River drainage. Extends the range ca. 40 km NW from the nearest known populations in Aiken County, South Carolina (Shoop 1964, Cat. Am. Amph. Rept. 8.1–8.2; Petranka 1998, Salamanders of the United States and Canada. Smithsonian Institute Press, Washington, D.C. 587 pp.). Specimen was captured within an isolated, non-alluvial depression wetland (ca. 0.25 ha) that floods during periods of heavy rain and dries completely by late summer. The majority of *A. talpoideum* captures within this wetland occurred from November 2000 to February 2001.

New county records (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.). Other than one unverified sight record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.), the Jackson County specimens are the first published records within Natural Divisions 4a and 4c (Hole and Germain 1994, Natural Divisions of Wisconsin Map. Wisconsin Dept. Natural Resources, Madison) of the Glacial Lake Wisconsin basin, characterized by pine and oak barrens, wet meadow and swamp forest, and sand soils. Salamanders were in communities where broadleaf trees (Maple, Oak, Alder, Birch) were co-dominant with White Pine.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA (e-mail: gsc@mpm.edu), and **KATHRYN KIRK**, Wisconsin Department of Natural Resources, Bureau of Endangered Resources, Box 7921, Madison, Wisconsin 53707, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: WISCONSIN: CRAWFORD CO: Sec. 19, T8N, R4W, crossing gravel road near oxbow of Kickapoo River. 7 March 2000. Jim Barnes. MPM 31623; MARQUETTE CO: Sec. 6, T16N, R11E, pond 1.75 miles east of Germania on Eagle Road. 12 May 1999. Matt Wright. MPM 30362. Both verified by Robert W. Henderson. New county records (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.; Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.).

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA; e-mail: gsc@mpm.edu.

PLETHODON WEHRLEI (Wehrle's Salamander). USA: NORTH CAROLINA: WILKES CO: 12.2 km NW Traphill. 21 May 2001. J. C. Beane, J. P. Cecil, D. S. Dombrowski, and D. W. Herman. North Carolina State Museum of Natural Sciences (NCSM 61868). Verified by Alvin L. Braswell. One of 11 specimens observed. M. E. Dorcas originally observed and photographed three specimens at this locality on 24 May 1999. New county record; extends range 18 km WSW of nearest records in Alleghany and Surry counties (Beane and Somers 1994, Herpetol. Rev. 25: 31). Species is now known from four counties in North Carolina. Collected under permit NC-2001-ES-40.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, 4301 Reedy Creek Road, Raleigh, North Carolina 27607, USA, **DANIEL S. DOMBROWSKI** and **DENNIS W. HERMAN**, North Carolina State Museum of Natural Sciences, 11 West Jones Street, Raleigh, North Carolina 27601, USA, **JOHN P. CECIL**, North Carolina Wildlife Resources Commission, 91 White Oak Road, Arden, North Carolina 28704, USA, and **MICHAEL E. DORCAS** and **SHANE D. LINDSAY**, Department of Biology, Davidson College, Box 1719, Davidson, North Carolina 28036, USA.

ANURA

BATRACHYLA NIBALDOI (Nibaldo's Wood frog). CHILE: XI REGION DE AYSEN: General Carrera Province, Laguna San Rafael National Park (46°38'S, 73°51'S). 23 January–9 February 1999. H. Díaz-Páez and C. Williams. Museo de Zoología de la Universidad de Concepción (MZUC 25281–91; MZUC 25293–302). Verified by R. Formas. Numerous calling males were found on the humid soil surface along the borders of streams surrounded by dense low vegetation. First record for the Laguna San Rafael National Park; extends the known distribution ca. 153 km SW from type locality at Puente Traihuanca (Formas 1997, Herpetologica 53:6–13).

Submitted by **HELEN DÍAZ PÁEZ**, Departamento de Zoología, Facultad de Ciencias Naturales y Oceanográficas, Universidad de Concepción, Casilla 160-C, Concepción, Chile, and **CLAIR WILLIAMS**, Durrell Institute of Conservation and Ecology (DICE), University of Kent, Canterbury, Kent, CT2, United Kingdom.

BUFO HAEMATITICUS: VENEZUELA: ESTADO ZULIA: Río Socuy, Sierra de Perijá. 12 April 1990. Francisco Herrera. Museo de Biología, Universidad Central de Venezuela, Caracas (MBUCV 6630). Verified by John D. Lynch. First record for country and easternmost for the species. *B. hematiticus* is distributed from Central América from eastern Honduras to Costa Rica and Panamá through western and central Colombia to western Ecuador (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.). The presence of this species in the eastern slopes of Sierra de Perijá indicates that some Chocoan elements occur in the Maracaibo Lake Basin, as well as some Amazonian elements, like *Lithodytes lineatus* (Barros and Barrio 2001, Herpetol. Rev. *In press*).

Submitted by **CÉSAR L. BARRIO-AMORÓS**, Fundación AndígenA, Apartado Postal 210, 5101-A Mérida, Venezuela; e-mail: cesarlba@yahoo.com.

BUFO HOUSTONENSIS (Houston Toad). USA: TEXAS: LEE CO: 2.7 mi S jct. Lee County Road 331 and CR 333 on CR 333 (30°18'46.1"N, 97°09'08.9"W). 2 April 2001. James R. Dixon and Michael R. J. Forstner. Verified by R. Kathryn Vaughn. TCWC 84556. DOR. Represents first recorded occurrence of this endangered species in Lee County (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **MICHELE A. GASTON**, Department of Biol-

ogy, Southwest Texas State University, San Marcos, Texas 78666, USA (e-mail: mg45447@swt.edu), **JAMES R. DIXON**, Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843, USA, and **MICHAEL R. J. FORSTNER**, Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA (e-mail: mf11@swt.edu).

ODONTOPHRYNUS LAVILLAI. ARGENTINA: SAN JUAN: Valle Fértil Department, 137.5 km from San Juan (city) on Las Tumanas, Las Tumanas River (30°52'S, 67°19'W, 750 m elev). 25 February 2001. J. H. Villavicencio and M. G. Cánovas. Herpetological Collection Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 545). Verified by Juan Carlos Acosta. First province record; extends the known range ca. 350 km SW from the nearest locality of Sierra de Guasayán, Choya Departament, Santiago del Estero Province, the type locality (Cei 1985, Cuad. Herpetol. 1[5]:1–13).

Submitted by **JOSE HECTOR VILLAVICENCIO** and **MARIA GABRIELA CANOVAS**, Departamento de Geofisica y Astronomía. F.C.E.F. y N. Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina; e-mail (MGC): dgocanovas@sinectis.com.ar.

PSEUDACRIS CRUCIFER CRUCIFER (Northern Spring Peeper). USA: WISCONSIN: Dodge Co: SE 1/4 Sec. 5, T13N, R13E, calling from south of Lake Emily. 20 April 2001. Jack and Holly Bartholmai. MPM 32932. Verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.; Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.). Verifies reported observations from Dodge County Wisconsin Frog and Toad Survey Routes (Mossman et al. 1998, *In* M. J. Lannoo [ed.], Status and Conservation of Midwestern Amphibians, pp. 169–198. Univ. Iowa Press, Iowa City).

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA; e-mail: gsc@mpm.edu.

PSEUDACRIS STRECKERI (Strecker's Chorus Frog). USA: ARKANSAS: Pulaski Co: (N34.81341°, W92.40218°), Two Rivers Park. 12 March 2001. K. J. Irwin and L. K. Irwin. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26099). Verified by Stanley Trauth. Adult male calling in flooded park field. Syntopic species associates were *Pseudacris crucifer* and *Pseudacris feriarum*. First record for county and represents the most southeasterly record for the species in the state. (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **KELLY J. IRWIN**, Arkansas Game & Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us), and **LISA K. IRWIN**, 103 Brooke Drive, Perryville, Arkansas 72126, USA.

RANA GLANDULOSA (Rough-sided Frog). INDONESIA: NATUNA ISLANDS: Bunguran Island (4°00'N, 108°15'E). August 1928. F. N. Chasen. Raffles Museum of Biodiversity Research Zoological Reference Collection (ZRC.1.613, adult female, SVL 84.7 mm). Verified by Kelvin K. P. Lim. New island record; not previously recorded from the Natunas (Van Kampen 1923, The Amphibia of the Indo-Australian Archipelago. E. J. Brill, Leiden, xii + 304 pp.).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260; e-mail: scip0132@nus.edu.sg.

RANA PALUSTRIS (Pickerel Frog). USA: ARKANSAS: Phillips Co: (N34.57202°, W90.59502°), SE 1/4, Sec. 29, R5E, T1S, St. Francis National Forest. 3 March 2001. Ron Bonett, Carol Spence, L. K. Irwin, and K. J. Irwin. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26098). Verified by Stanley Trauth. Subadult found under leaves on gravel substrate spring outflow at base of eastern versant of Crowley's Ridge. Syntopic species associates were *Acris crepitans, Rana clamitans,* and *Rana sphenocephala*. First record for Phillips County (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **RON BONETT**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA (e-mail: desmog_2000@yahoo.com), **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us), **CAROL SPENCE**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA, and **LISA K. IRWIN**, 103 Brooke Drive, Perryville, Arkansas 72126, USA.

RANA SYLVATICA (Wood Frog). USA: TENNESSEE: Grundy Co: Savage Gulf State Natural Area (35°28'01"N, 85°36'02"W). 3 May 2001. Stephen T. Samoray and Kurt J. Regester. Austin Peay State University Museum (APSU Color Photograph 3273). Verified by A. Floyd Scott. One adult found on Connector Trail ca. 1 km south of Hobbs cabin. New county record (Redmond and Scott 1996, Austin Peay State Univ. Center Field Biol. Misc. Publ. 12:1–94); extends range ca. 45 km SW of previously recorded limit in Bledsoe County.

Submitted by **STEPHEN T. SAMORAY** and **KURT J. REGESTER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

SCINAX NASICUS. ARGENTINA: CÓRDOBA: Río Cuarto (33°08'S, 64°22'W), 434 m elev. 9 March 2001. N. E. Salas. Herpetological Collection of Universidad Nacional de Río Cuarto, Ecología. (UNRC-ECO 690). Verified by R. Martori. Previously recorded in Argentina from Jujuy, Salta, Formosa, Chaco, Misiones, Córdoba, Santiago del Estero, Tucumán, Corrientes Santa Fe, Entre Ríos, and Buenos Aires (Cei 1980, Amphibians of Argentina. Monit. Zool. Ital. [N. S.], Monogr. 2:1–609; Lavilla et al. 2000. *In* Lavilla et al. [eds.], Categorización de los Anfibios y Reptiles de la República Argentina, pp. 11–34. Asociación Herpetológica Argentina). In Córdoba, was reported from the northeastern departments of Sobremonte, Río Seco, Tulumba, and San Justo (di Tada et al. 1996. *In* I. E. di Tada and E. H. Bucher [eds.], pp. 191–213. Ed. UNRC), and from the eastern departments of General San Martín and Unión (Rozzi Giménez and Gallego 1998, Cuad. Herpetol. 14[2]:169). First report for southern Córdoba and extends distribution 130 km south.

Submitted by **NANCY E. SALAS** and **ISMAEL E. DI TADA**, Departamento de Ciencias Naturales, Facultad de Ciencias Exactas,

Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto, Km 601, Ruta N°36 (X5804BYA), Río Cuarto, Córdoba, Argentina; e-mail (NES): nsalas@exa.unrc. edu.ar.

TESTUDINES

APALONE SPINIFERA SPINIFERA (Eastern Spiny Softshell). USA: WISCONSIN: Vilas Co: SE 1/4 NW 1/4 Sec. 7, T42N, R5E, Benson Lake. 13 August 1997. Jim Cox, Jim Zarzycky, Bruce Bacon. MPM Photograph 657. Verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.; Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.); first published record within Natural Divisions 4a and 4c (Hole and Germain 1994, Natural Divisions of Wisconsin Map. Wisconsin Dept. Natural Resources, Madison).

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA; e-mail: gsc@mpm.edu.

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: NEW MEXICO: Debaca Co: Sumner Lake State Park, Pecos River, ca. 0.5 km downstream of dam; E 1/2 Sec. 2, T4N, R24E, UTM Zone 13, E556054, N3828590. Female, 24 cm curved carapace length. 5 May 2001. Charles W. Painter. University of New Mexico Museum of Southwestern Biology (MSB 62058). Verified by J. Tomas Giermakowski. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, **DONALD S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA, and **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: TEXAS: Cass Co: 3.2 km SW Hughes Springs off FM 250. 9 June 2001. Beverly K. Allen. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26159). Verified by Stanley E. Trauth. New county record. Helps fill hiatus in extreme northeastern Texas in the Ark-La-Tex region (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **BEVERLY K. ALLEN** and **CHRIS T. McALLISTER**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA.

CLAUDIUS ANGUSTATUS (Narrowbridge Musk Turtle). MEXICO: YUCATAN: Municipality of Celestún, 20 km E Celestún (20°51'36"N, 90°11'40"W). 20 September 2000. René Calderón and J. Rogelio Cedeño-Vázquez. Herpetological Collection, Museum of Zoology, El Colegio de la Frontera Sur campus Chetumal, Quintana Roo (ECO-CH-H 1692, 1710). Verified by Oscar Flores-Villela. Found in a temporary pond surrounded by tropical deciduous forest. First record for Yucatan; northernmost records for the species on the Yucatan Peninsula, extending the range more than 200 km north from the closest records in Campeche and Quintana Roo (Calderon Mandujano et al. *In Press*).

Submitted by **RENÉ CALDERON MANDUJANO**, **J. ROGELIO CEDEÑO-VÁZQUEZ**, and **CARMEN POZO**, Museo de Zoologia, El Colegio de la Frontera Sur, Unidad Chetumal, Apartado Postal 424, Cod. Postal 77000, Chetumal, Quintana Roo, México.

GOPHERUS POLYPHEMUS (Gopher Tortoise). USA: SOUTH CAROLINA: Aiken Co: Aiken Gopher Tortoise Heritage Preserve, a 565-ha scrub oak sandhill habitat located 10–12 km east of Windsor. 7 May 2001. Berkeley Boone. Georgia Museum of Natural History (GMNH 46764). Verified by Steve Bennett. Hatchling specimen (CL = 50 mm; PL = 45 mm). Locality is a northern range extension in South Carolina of more than 120 km (from Tillman Sand Ridge in Jasper County). Neither gopher tortoises nor abundant wiregrass (*Aristida beyrichiana*) were believed to occur between the Savannah River and Columbia, South Carolina (Auffenburg and Franz 1982, *In* Bury [ed.]. North American Tortoises: Conservation and Ecology. Pp. 95–126. U. S. Fish Wildlife Res. Rep. 12), an area of sand hills known as the Fall Line Hills.

Submitted by **ERIN E. CLARK** and **RIA N. TSALIAGOS**, Savannah River Ecology Laboratory, University of Georgia, Aiken, South Carolina 29802, USA (e-mail: clark@srel.edu or tsaliagos@srel.edu), and **ALBERT B. PITTMAN**, South Carolina Department of Natural Resources, Columbia, South Carolina 29202, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA KOHNII (Mississippi Map Turtle). USA: ARKANSAS: Clark Co: Caddo Valley off US 67 bridge in Caddo River. 5 June 2001. Zachary D. Ramsey. Henderson State University Collection (HSU 841). Verified by Stanley E. Trauth. New county record and first specimen from lower Caddo River, a tributary of the Ouachita River and impoundment of DeGray Lake. This turtle is known from the Ouachita River watershed in neighboring Hot Spring County (Trauth, Robison, and Plummer, ms in prep.).

Submitted by **ZACHARY D. RAMSEY**, **CHRIS T. McALLISTER**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA, and **RENN TUMLISON**, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA KOHNII (Mississippi Map Turtle). USA: VIRGINIA: City of Newport News: Lake Maury. 23 May 1995. David Dowling. Virginia Museum of Natural History (VMNH 8866). Verified by Alan H. Savitzky. Two specimens captured by Virginia Department of Game and Inland Fisheries personnel using electroshocking gear to assay fish populations. One specimen killed and preserved and one held alive in captivity. Existence of established population hypothesized by Mitchell and Reay (1999, Atlas of Amphibians and Reptiles in Virginia. Virginia Dept. Game Inland Fish. Spec. Publ. No. 1:v + 122 pp.). Confirmation of an established population made by observations of basking turtles with a Celestron spotting scope from September 2000 to May 2001 by Barbara A. Savitzky. Verified by Alan H. Savitzky. Found basking throughout Lake Maury, in numbers as high as any native species of emydid turtle. Juveniles, as

well as male and female adults, were observed. First record of an established population in Virginia. This population is well out of the natural range of *G. p. kohnii* and is likely the result of anthropogenic dispersal via the pet trade. Other populations of this species are probable in southeastern Virginia, as specimens have been found elsewhere in Newport News and across the James River in Norfolk, Virginia (Mitchell 1994, The Reptiles of Virginia. Smithsonian Inst. Press, Washington, D.C., viii + 352 pp.).

Submitted by **BARBARA A. SAVITZKY**, Christopher Newport University, Newport News, Virginia 23606, USA, and **JOSEPH C. MITCHELL**, University of Richmond, Richmond, Virginia 23173, USA.

KINOSTERNON FLAVESCENS (Yellow Mud Turtle). USA: TEXAS: LEE CO: 1.75 mi S jct. Lee County Roads 331 and CR 333 on CR 333 (30°19'04.7"N, 97°08'10.9"W). 20 April 2001. Michele Gaston, Ellen Gaston, James R. Dixon, and Michael R. J. Forstner. TCWC 84562. Verified by R. Kathryn Vaughn. DOR; first record from Lee County (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press. 421 pp.).

Submitted by **MICHELE GASTON** (e-mail: mg45447@swt.edu) and **ELLEN GASTON**, Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA, **JAMES R. DIXON**, Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843, USA, **LEE SHERROD**, Horizon Environmental Services, Inc., Austin, Texas 78716, USA, and **MICHAEL R. J. FORSTNER** (e-mail: mf11@swt.edu), Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA.

TRACHEMYS SCRIPTA (Slider). USA: TEXAS: LEE CO: 2.25 mi W jct. Lee County Road 310 and CR 309 on CR 309 (30°20'46.1"N, 97°06'52.7"W). 20 April 2001. Michele Gaston, Ellen Gaston, James R. Dixon, and Michael R. J. Forstner. TCWC 84560–61. Verified by R. Kathryn Vaughn. Collected from roadside; first record for the county (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M University Press. 421 pp.).

Submitted by **MICHELE GASTON** (e-mail: mg45447@swt.edu) and **ELLEN GASTON**, Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA, **JAMES R. DIXON**, Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843, USA, **LEE SHERROD**, Horizon Environmental Services, Inc., Austin, Texas 78716, USA, and **MICHAEL R. J. FORSTNER** (e-mail: mf11@swt.edu), Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA.

LACERTILIA

ANISOLEPIS GRILLI. BRAZIL: RIO GRANDE DO SUL: Municipality of Santo Ângelo (28°18'S, 54°08'W). 6 March 2001. L.H. Cappellari. Museu de Ciências e Tecnologia da Pontifícia Universidade do Rio Grande do Sul (MCP 12352). Verified by Thales de Lema. Extends geographic range 175 km SE from Dos de Mayo, Departamento Cainguás, Misiones, Argentina and 280 km NW from Garibaldi, Rio Grande do Sul, Brazil (Etheridge and Williams 1991, Bull. Mus. Comp. Zool. 152[5]:317–361).

Submitted by **LIZE HELENA CAPPELLARI**, **RAFAEL LUCCHESI BALESTRIN**, Laboratório de Herpetologia, Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul, Avenida Ipiranga 6681, CEP 90619-900, Porto Alegre, Rio Grande do Sul, Brazil, and **ELISÂNGELA CRISTINA BEUREN**, Universidade Regional Integrada do Alto Uruguai e das Missões, Santo Ângelo, Rio Grande do Sul, Brazil.

ANNIELLA GERONIMENSIS (Baja California Legless Lizard). MEXICO: BAJA CALIFORNIA: Isla San Martin, 30°29'03"N, 116°06'00"W. 23 January 2001. José Ángel Sánchez-Pacheco. Verified by Lee Grismer. La Sierra University Photographic Collection (LSUPC L5959–60), SVL = 115 mm. Species occurs through a small coastal area across from the island, and on Isla San Gerónimo to the south (Grismer 1993, Herpetol. Nat. Hist. 1[2]:1–10). First record for the island. Specimen was found under a 40-cm rock in a sandy area with sparse Frutilla (*Lycium* sp.) on the northwestern side of the island.

Submitted by **JOSÉ ÁNGEL SÁNCHEZ-PACHECO**, Grupo de Ecologia y Conservación de Islas, Apartado Postal 162, 22791 Punta Banda, Baja California, Mexico, and **ERIC MELLINK**, Centro de Investigación Cientifica y de Educación Superior de Ensenada, Baja California, Apartado Postal 2732, 22800 Ensenada, Baja California, Mexico.

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: CLAY CO: jct. Florida Rt. 21 and Lakeview Road. 24 June 2001. Josiah Townsend. UF 124687. Verified by F. Wayne King. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Two. Lizards, Turtles, and Crocodilians. Second Ed. Windward Publ., Miami. 176 pp.).

Submitted by **JOSIAH H. TOWNSEND** (e-mail: jtownsend @flmnh.ufl.edu), Division of Herpetology, Florida Museum of Natural History, Gainesville, Florida 32611, USA, and **CORY R. LINDSAY**, Department of Biology, Wayne State College, Wayne, Nebraska 68787, USA.

CNEMIDOPHORUS TIGRIS (Western Whiptail). MEXICO: SINALOA: Farallón de San Ignacio, 25°26'13"N, 109°22'46"W. 6 March 2001. Marco Antonio González-Bernal. Colección de Vertebrados, Universidad Autónoma de Aguascalientes (CZRUAA 299). SVL = 70.9 mm. Verified by Brad Hollingsworth. Species occurs in a wide area of the southwestern United States and western Mexico, including northwestern coastal Sinaloa (Hardy and McDiarmid 1969, The Amphibians and Reptiles of Sinaloa, Mexico. Univ. Kansas Publ. Mus. Nat. Hist. 18:39–252; Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin, Boston, Massachusetts). First record for the island, where it is common.

Submitted by **MARCO ANTONIO GONZÁLEZ-BERNAL**, Escuela de Biología, Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, Mexico, **ERIC MELLINK**, Centro de Investigación Científica y de Educación Superior de Ensenada, B.C., Apartado Postal 2732, 22800 Ensenada, B.C., Mexico, and **CARLOS PAYÁN-ESQUERRA**, Universidad Católica de Culiacán, Culiacán, Sinaloa, Mexico.

EUMECES FASCIATUS (Five-lined Skink). USA: WISCONSIN: MONROE CO: Three records: MPM 30298. NE 1/4 SE 1/4 Sec. 11, T19N, R1E, west side Crescent Road, ca. 100 m south of Rt. EW. 24 June 1998. Gary S. Casper; MPM Photograph 625; NE 1/4 NW 1/4 Sec. 8, NE 1/4 NW 1/4 Sec. 8, T19N, R1W, along railroad tracks. September 1997. James Burnham; MPM Photograph 626. NE 1/4 SW 1/4 Sec. 1, T19N, R2W, along railroad tracks. September 1997. James Burnham. All verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.). Extends range slightly south and west from records mapped by Vogt (1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.). Within sand soils of Glacial Lake Wisconsin basin, where locality records are clustered.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA(e-mail: gsc@mpm.edu), and **JAMES BURNHAM**, Wisconsin Department of Natural Resources, Bureau of Endangered Resources, Box 7921, Madison, Wisconsin 53707, USA.

EUMECES LATICEPS (Broad-headed Skink). USA: TEXAS: NAVARRO CO: 11.2 km W Corsicana off county road SW 1120 and about 1.6 km from FMR 2452. 7 may 2001. J. Dennis Hawk. Navarro College specimen collection (NC 2001.5.8 1L). Verified by Thomas Vance. Adult male; killed by house cat and mauled, but clearly identifiable; new county record within the hiatus of its central Texas range (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp).

Submitted by **J. DENNIS HAWK**, Department of Science, Navarro College, Corsicana, Texas 75110, USA.

HEMIDACTYLUS GARNOTII (Indo–Pacific Gecko). USA: FLORIDA: FLAGLER CO: on the grounds of the Whitney Laboratory, adjacent to Marineland. 13 June 2001. Jessica Roberts-Misterly. UF 124688. Verified by F. Wayne King. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Two. Lizards, Turtles, and Crocodilians. Second Ed. Windward Publ., Miami. 176 pp.).

Submitted by **CORY R. LINDSAY**, Department of Biology, Wayne State College, Wayne, Nebraska 68787, USA, and **JOSIAH H. TOWNSEND**, Division of Herpetology, Florida Museum of Natural History, Gainesville, Florida 32611, USA; e-mail: jtownsend@flmnh.ufl.edu.

Submitted by **JOSIAH H. TOWNSEND** and **ANTHONY T. REPPAS**, Division of Herpetology, Florida Museum of Natural History, Gainesville, Florida 32611, USA; e-mail: jtownsend @flmnh.ufl.edu.

LIOLAEMUS USPALLATENSIS. ARGENTINA: SAN JUAN: Departmento Iglesia, Barrialito, 120 km from San Juan (city) on Ruta Provincial 436 (30°34'42"S, 69°06'26"W) January 2000. R. G. Buff, P. F. Gomez, J. A. Marinero, and H. J. Villavicencio. Herpetological Collection, Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 447–448, 507–508). Verified by J. C. Acosta. Extends known range (Acosta et al. 2001, Cuad. Herpetol. 14[2]:161) ca. 61 km northeast of nearest locality (20 km northwest from Villa Nueva, Calingasta Department, San Juan Province).

Submitted by **RICARDO BUFF**, **PABLO GOMEZ**, **JOSE MARINERO**, and **JOSE VILLAVICENCIO**, Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, F.C.E.F. y N., Universidad Nacional de San Juan, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina.

PSEUDOGONATODES GUIANENSIS. VENEZUELA: AMAZONAS: interior valley in Serranía de Unturán, 01°48'65"N, 65°24'20"W, 200 m elev. 27 October 1992. César Molina. Museo de Historia Natural La Salle, Caracas (MHNLS 13980). Verified by Gilson Rivas. Specimen found at 1630 h on leaf litter near a ravine. First state record; extends known distribution 700 km SW inside Venezuela. Previously recorded in Venezuela from northeastern Bolívar (Gorzula and Señaris 1998, Scientia Guaianæ 8:xviii + 302 pp).

Submitted by **CÉSAR MOLINA**, Sectión of Herpetology, Museo de Historia Natural La Salle, Apartado 1039, Caracas 1010-A, Venezuela; e-mail: crmolina@mixmail.com.

SCELOPORUS COZUMELAE (Cozumel Spiny Lizard). MEXICO: CAMPECHE: Municipality of Calkini, Isla Arena Village (20°41'37"N, 90°27'13"W). 24 October 2000. René Calderón and J. Rogelio Cedeña-Vázquez. Herpetological Collection, Museum of Zoology, El Colegio de la Frontera Sur campus Chetumal, Quintana Roo (ECO-CH-H 1731–34). Verified by Oscar Flores-Villela. First record for Campeche; closest previous locality record was a few kilometers north in Celestún, Yucatan (Lee 1996, The Amphibians and Reptiles of the Yucatán Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.)

Submitted by **J. ROGELIO CEDEÑO-VÁZQUEZ**, **RENÉ CALDERON MANDUJANO**, and **CARMEN POZO**, Museo de Zoologia, El Colegio de la Frontera Sur, Unidad Chetumal, Apartado Postal 424, Cod. Postal 77000, Chetumal, Quintana Roo, Mexico.

UROSAURUS ORNATUS (Tree Lizard). MEXICO: SINALOA: Farallón de San Ignacio, 25°26'13"N, 109°22'46"W. 6 March 2001. Marco Antonio González-Bernal. Verified by Brad Hollingsworth. Colección de Vertebrados, Universidad Autónoma de Aguascalientes (CZRUAA) 279, SVL = 55.1 mm and CZRUAA 280, SVL = 52.4 mm. Species occurs in a wide area of the southwestern United States and western Mexico, including northwestern coastal Sinaloa (Hardy and McDiarmid 1969, The Amphibians and Reptiles of Sinaloa, México. Univ. Kansas Publ. Mus. Nat. Hist. 18:39–252; Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin, Boston, Massachusetts). First record for the island, where it is common on rocky outcrops of, at least, the flat top.

Submitted by **MARCO ANTONIO GONZÁLEZ-BERNAL**, Escuela de Biología, Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, Mexico, **ERIC MELLINK**, Centro de Investigación Científica y de Educación Superior de Ensenada, B.C., Apartado Postal 2732, 22800 Ensenada, B.C., Mexico, and **CARLOS PAYÁN-ESQUERRA**, Universidad Católica de Culiacán, Culiacán, Sinaloa, Mexico.

SERPENTES

ARIZONA ELEGANS ARENICOLA (Texas Glossy Snake). USA: TEXAS: Nacogdoches Co: (31°49'50"N, 94°37'57"W). 7 June 1999. TCWC 82778. Verified by R. Kathryn Vaughan. New county record. (Dixon 2000, Amphibians and Reptiles of Texas. Second edition. Texas A&M Univ. Press, College Station. 421 pp.) This snake, and three additional *A. elegans* that were released, were captured in a funnel trap in northern Nacogdoches County in the Carrizo Sand Formation. This record extends the known range ca. 70 km southeast of the nearest historical locality in Smith County. Previous records exist for Henderson and northern Anderson counties on soils derived from the Queen City and Carrizo Sand Formations and from Smith County on soils derived from the Sparta Sand Formation. Extends known range to soils derived from a band of the Carrizo Sand Formation that extends east from northern Nacogdoches County and southern Rusk County. This eastern extension of this chiefly western species is similar to that of other western species (e.g., *Phrynosoma cornutum, Sceloporus olivaceus, Heterodon nasicus,* and *Hypsiglena torquata*) that occur on these sand formations in eastern Texas.

Submitted by **CHRISTOPHER S. COLLINS, D. CRAIG RUDOLPH, DANIEL SAENZ**, and **TONI TREES**, Wildlife Habitat and Silviculture Laboratory, Southern Research Station, USDA Forest Service, Nacogdoches, Texas 75962, USA, and **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

CROTALUS MOLOSSUS (Black-tailed Rattlesnake). USA: ARIZONA: Gila Co: Mogollon Rim, Christopher Creek (Sec. 30, T11N, R13E). 26 June 2000. Dylan Holycross. University of Kansas photo voucher (KU Color Slide 11825). Verified by Andrew T. Holycross. Specimen was photographed in a rockpile in a steep canyon forested in juniper and pinyon; extends range about 20 km northeast (Lowe et al. 1986, The Venomous Reptiles of Arizona. Publ. Arizona Game and Fish Department. 115 pp.).

Submitted by **DYLAN A. T. HOLYCROSS**, 2108 East Colgate Drive, Tempe, Arizona 85283, USA, and **LAWRENCE J. SMITH**, 41 Manor Road North, Hinchley Wood, Surrey, KT10 OAA, England.

CROTALUS MOLOSSUS (Black-tailed Rattlesnake). USA: ARIZONA: Mohave Co: Tuckup Canyon. 27 April 2000. Sally Underwood. UAZ 52983-PSV. Specimen photographed in bed of Tuckup Canyon near confluence with Cottonwood Canyon. Represents third vouchered locality from the North Rim of the Grand Canyon; extends range *ca.* 18 km ENE of nearest vouchered north rim sighting at Tuweep (Koenig 2000, Herpetol. Rev. 31:254–255). The remaining record is from Parashant Canyon (Koenig *op cit.*). Only two other vouchers (both from the south rim) document *C. molossus* from significant depths in the Grand Canyon (Brown 2000, Herpetol. Rev. 31:55; McKee and Bogert 1934, Copeia 1934:178–180). Although *C. molossus* is infrequently encountered within Grand Canyon, these vouchered localities along with sightings from Green Spring Canyon (K. Abbott, pers. comm.) and from the vicinity of Mt. Trumbull (H. Koenig, pers. comm.) suggest the species occurs along much of the rims of the Shivwits and Kanab plateaus and may occur on the Sanup Plateau.

Submitted by **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA.

CROTALUS TIGRIS (Tiger Rattlesnake). USA: ARIZONA: Maricopa Co: Maricopa Mountains, ca. 7 mi N Shawmut (railroad siding). 15 May 2001. James A. Badman. ASU 33150. Verified by A. T. Holycross. Specimen found in east-facing canyon. First record from the Maricopa Mountains (A. T. Holycross, pers. comm.) and a slight westward extension of range as mapped by Lowe et al. (1986, The Venomous Reptiles of Arizona. Publ. Arizona Game and Fish Dept., Phoenix. 115 pp.).

Submitted by **JAMES A. BADMAN**, Animal Care Program, Arizona State University, Tempe, Arizona 85287-0608, USA.

DIADOPHIS PUNCTATUS (Ring-necked Snake). USA: NEW MEXICO: Debaca Co: Sumner Lake State Park; along upper reaches of Pecos Arm of Lake Sumner; T5N R24E SW1/4 Sec 18; UTM Zone 13 E551081 N3834616. Female, SVL 135 mm, tail 25 mm. 5 May 2001. Donald S. Sias. University of New Mexico Museum of Southwestern Biology (MSB 62059). Verified by J. Tomas Giermakowski. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DONALD S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA, **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

DIADOPHIS PUNCTATUS (Ring-necked Snake). USA: WISCONSIN: Jackson Co: NW 1/4 SE 1/4 Sec. 31, T20N, R2W. 9 September 1997. James Burnham. Verified by Robert W. Henderson. MPM Photograph 610. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.). Ventral pattern intermediate between *D. p. arnyi* and *D. p. edwardsii*. Ca. 50 km from nearest *D. p. arnyi* records to the southwest, and 75 km from nearest *D. p. edwardsii* records to the north (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.). In ecotone where the unglaciated southwestern uplands meet the central Glacial Lake Wisconsin plain. Collected in an abandoned shale pit within Oak/Pine community.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA, and **JAMES BURNHAM**, Wisconsin Department of Natural Resources, Bureau of Endangered Resources, Box 7921, Madison, Wisconsin 53707, USA.

DIPSAS LATIFRONTALIS (Venezuelan Snail-eater). VENEZUELA: ESTADO ARAGUA: Municipio Mario Briceño Iragorri, Rancho Grande, Parque Nacional Henri Pittier. 1100 m elev. 17 August 1989. R. García. Museo del Instituto de Zoología Agrícola, Maracay (MIZA 14-487). Verified by Dinora Sánchez; "El Helipuerto," Parque Nacional Henri Pittier, Maracay - Ocumare de la Costa road, 850 m elev. 18 June 2000. Carlos Laucho. Colección de Anfibios y Reptiles, Laboratorio de Biogeografía, Universidad de Los Andes, Mérida (ULABG 4690). Verified by Dinora Sánchez; ESTADO CARABOBO: Municipio Guacara, Vigirima, El Guapo, Parque Nacional San Esteban. 15 August 1995. Marco Natera. ULABG 4147. Verified by Marco Natera; DISTRITO FEDERAL: Municipio Libertador, Boca de Tigre, Parque Nacional El Avila, 1800 m elev. 26 October 1996. Gilson Rivas. Museo de Historia Natural La Salle, Caracas (MHNLS 13305). Verified by Gilson Rivas; ESTADO MIRANDA: Municipio Guaicaipuro, Agua Fría dam, El Jarillo-Lagunetica Road. 22 July 1988. Jesús Manzanilla. MIZA 14-480. Verified by Dinora Sánchez; Municipio Páez, Caño Rico, El Bachiller, El Guapo. 12 August 1979. I. Borsini. MIZA 14-229. Verified by Dinora Sánchez; ESTADO VARGAS: Naiguatá mountains. January 1976. J. Sánchez y H. Ceballos. Museo de Ciencias Naturales de Caracas, Caracas (MCNC 6415, 6453). Verified by Luis Fernando Navarrete. New state records. Taxon was described based on a single specimen from Aricagua, Estado Mérida, in the Venezuelan Andes (Boulenger 1905, Ann. Mag. Nat. Hist., 7[15]:561; Roze 1966, La Taxonomía y Zoogeografía de los Ofidios de Venezuela. Edic. Biblioteca. Universidad Central de Venezuela, Caracas). Outside the Andes, there are several unvouchered literature records of the species from the Venezuelan Coastal Range, the "Cordillera de la Costa" (Test et al. 1966, Misc. Pub. Mus. Zool. Univ. Michigan 128:1–63; Silva and Valdez 1989, Acta Biol. Venezuelica 12[3–4]:88–97). The specimens reported herein constitute the first documented vouchers for this mountain range. One specimen (MIZA 14-229) represents the easternmost record for the taxon, extending the known range about 600 km NE from the type locality.

FARANCIA ABACURA (Mud Snake). USA: ARKANSAS: Perry Co: (N34.98921°, W92.76386°), NE 1/4, SW 1/4, Sec. 13, R17W, T4N, on Arkansas Rt. 300, 2 mi ENE jct. of Arkansas Rt. 300 and 9, Harris Brake Wildlife Management Area. 6 May 2001. K. J. Irwin and L. K. Irwin. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26097). Verified by Stanley Trauth. Adult male found DOR bounded by open, grass-covered dam on one side and bottomland hardwood forest on the other. First record for county and most northwesterly record for the species in the Arkansas River basin. (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **KELLY J. IRWIN**, Arkansas Game & Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us), and **LISA K. IRWIN**, 103 Brooke Drive, Perryville, Arkansas 72126, USA.

FARANCIA ABACURA (Mud Snake). USA: SOUTH CAROLINA: Greenville Co: Duncan Chapel Road at RR crossing, ca. 10 km N Greenville (34°55.209'N, 82°26.835'W), 300.9 m elev. 10 May 1979. Richard F. Trotta. Furman University Vertebrate Zoology Collection (FUVZC 106). Verified by J. Whitfield Gibbons. Male, ca. 61 mm SVL; first record for the county and first record northwest of the Fall Line, separating the Piedmont Physiographic Province from the Atlantic Coastal Plain Physiographic Province. Extends the range ca. 125 km (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Company, Boston. xviii + 450 pp.).

Submitted by **KATE INGRAM**, **TRAVIS W. PERRY**, and **TRAVIS J. RYAN**, Department of Biology, Furman University, Greenville, South Carolina 29613, USA; e-mail (TWP): travis.perry@furman.edu.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: COLORADO: Sedgwick Co: DOR on county road 29, 0.5 mile S jct. with I-76, UTM 0720052, 4533011. UNC-MNH 4098. Verified by Hobart M. Smith and David Chiszar. First county record (Hammerson 1999, Amphibians and Reptiles of Colorado. Second Ed. Univ. Colorado Press, Niwot. xxvii + 484 pp.). Extends known distribution in Colorado northeast by ca. 50 miles. Specimen is an intergrade between *L. t. gentilis* and *L. t. multistriata*.

Submitted by **AMY HOCKING, KRISTEN LUCKE, AMBER LAWSON,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, 501 20th Street, CB 92, Greeley, Colorado 80639-0017, USA; e-mail (SPM): spmacke@bentley.unco.edu.

LAMPROPLETIS TRIANGULUM TRIANGULUM (Eastern Milk Snake). USA: ILLINOIS: FULTON CO: Canton (40°33'N, 90.53'E, Canton Twp.). May 1954. Robert Schroder. HDW/NIU 1829 (former number RE 241, Putnam Musuem of History and Natural Sciences, Davenport, Iowa). Verified by Christine L. Chandler. New county record; not cited by Smith (1961, Bull. Illinois Nat. Hist. Surv. 28:1–298) or (Phillips et al. 1999, Illinois Nat. Hist. Surv. Manual 8:1–182).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

LICHANURA TRIVIRGATA TRIVIRGATA (Mexican Rosy Boa). USA: ARIZONA: MARICOPA CO: North Maricopa Mountains, 33°0'46"N, 112°27'37" W, 543 m elev. 10 May 2001. Thomas C. Brennan and Martin J. Feldner. University of Arizona Color Slide 53399-PSV. Verified by A. T. Holycross. Male (51 cm SVL, 113.4 g) collected at 2215 h in a dry wash surrounded by upland Sonoran Desert vegetation growing among granitic rocks and gravelly soils. A second specimen was captured 14 May 2001 at the same location by Jeff S. Miller and Thomas C. Brennan. Coloration, pattern, and scutellation of both specimens are consistent with descriptions for the nominate race (A. T. Holycross, pers. comm.). Both specimens have very dark chocolate uniform dorsal and lateral stripes, a chocolate "mustache" between the eye and nare, and dark markings around the vent. Both specimens largely lack the ventral stripes formed by mottling on the lateral aspect of the ventrals (often present in *L. t. gracia*). The first specimen has 14 left and right supralabials, 15 left infralabials, 14 right infralabials, has slightly enlarged preoculars, and lacks infraoculars. Recent mtDNA sequence analysis conducted by Dustin Wood (Department of Biology, San Diego State University) confirms that the specimens reported herein are *L. t. trivirgata* (using current taxonomy). Morphology and mtDNA are concordant.

In a recent survey of ca. 63 institutional and private collections, all vouchered specimens of *L. t. trivirgata* from Arizona were collected on Organ Pipe Cactus National Monument (A. T. Holycross, pers. comm.). Fowlie (1965. The Snakes of Arizona. Azul Quinta Press, Fallbrook, California) reported a specimen (no subspecific designation) from the Growler Mountains, but did not provide voucher information. The specimens reported herein represent a northward range extension of ca. 110 km.

Submitted by **THOMAS C. BRENNAN**, 13201 South Wakial Loop, Apt. 2139, Phoenix, Arizona 85044, USA, and **MARTIN J. FELDNER**, 1918 East Redfield Road, Tempe, Arizona 85283, USA.

MASTICOPHIS TAENIATUS (Striped Whipsnake). USA: NEW MEXICO: DEBACA CO: Sumner Lake State Park, East River Campground; NE 1/4 Sec. 2, T4N, R24E, UTM Zone 13 E556229, N3829140. DOR Female, SVL 115.5 cm, tail 44 cm (tail tip missing). 6 May 2001. Charles W. Painter. University of New Mexico Museum of Southwestern Biology (MSB 62057). Verified by J. Tomas Giermakowski. New county record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA, and **DONALD S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

NERODIA SIPEDON PLEURALIS (Midland Water Snake). USA: FLORIDA: LIBERTY CO: Sweetwater Creek (30°30'631"N; 84°54'113"W). 7 April 2001. F. Wayne King. UF 123361. Verified by Dan Janes. New county record (Ashton and Ashton, 1988, Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second Ed. Windward Publ., Miami. 176 pp.). First verified record of this species from east of the Apalachicola River in Florida.

Submitted by **JOSIAH H. TOWNSEND** and **F. WAYNE KING**, Division of Herpetology, Florida Museum of Natural History, Gainesville, Florida 32611, USA; e-mail (JHT): jtownsend @flmnh.ufl.edu.

RHADINAEA TAENIATA AEMULA (Mimic Pine-oak Snake). MEXICO: MORELOS: Municipio de Tetela del Volcán, 5 km NE of Tetela del Volcán, 2250 m elev. 14 June 1997. A Zaldivar-Riverón. MZFC 11822. Verified by A. Nieto-Montes de Oca. Adult specimen captured at midday while swimming in a small stream near agricultural field around a pine-oak forest. Extends geographic range in the state of Morelos about 60 km east from the nearest records (Myers 1974, Bull. Am. Mus. Nat. Hist. 153:1–262).

Submitted by **ALEJANDRO ZALDIVAR-RIVERÓN** and **EDMUNDO PÉREZ-RAMOS**, Museo de Zoologia, Facultad de Ciencias, Universidad Nacional Autónoma de México, Apartado Postal 70–399, México 04510, D.F., Mexico; e-mail (AZR): azr1@hp.fciencias.unam.mx.

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Red-bellied Snake). USA: WISCONSIN: MARQUETTE CO: SW 1/4 NE 1/4 Sec. 1, T14N, R10E, on gravel dike road at south side of dam on Grand River, Grand River Wildlife Area. 10 August 1999. Jerry Reetz. MPM 31624. Verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 87 pp.; Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Pub. Mus., Milwaukee. 205 pp.) within expected range.

Submitted by **GARY S. CASPER**, Section of Vertebrate Zoology, Milwaukee Public Museum, 800 West Wells Street, Milwaukee, Wisconsin 53233, USA (email: gsc@mpm.edu).

UROMACERINA RICARDINII (Liana Snake): BRAZIL: BAHIA: Municipality of Barra do Choça, Recanto da Adriana farm (14°57'32"S, 40°32'56"W, ca. 850 m elev.). 13 November 1999 to 5 April 2000. J. O. Ruas. Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia (MZUESC 97); Municipality of Arataca, Monte Sião farm (15°09'38"S, 39°18'07"W, 500–600 m elev.). 20 March to 10 May 2001. Collector unknown.

MZUESC 1131. Specimens were captured by different collectors but the precise dates of capture are unknown. Dates indicate periods between the visits to the farms. Both verified by Miguel Trefaut Rodrigues. Previously, species was known from the states of Rio de Janeiro, São Paulo, Paraná (Hoge 1957/58, Mem. Inst. Butantan 28:77–82) and Rio Grande do Sul (Lema 1973, Iheringia 44:64–73), with an apparently isolated population in Amazonian forest in the state of Pará (Cunha and Nascimento 1982, Bol. Mus. Para. Emílio Goeldi 113:1–9). In the Atlantic forest, the northern recorded limit was latitude 20°24'36"S in the state of Espírito Santo (Zamprogno 1997, Herpetol. Rev. 284:211). This discovery from northeastern Brazil extends the range in the Atlantic forest 600 km to the north.

New County Records for Amphibians from Bledsoe County, Tennessee

WAYNE H. SCHACHER
Natural Resource Services, 942 Fowler Street
Clinton, Tennessee 37716, USA
e-mail: whschacher@natreserv.com

and

T. HILL HENRY
Regional Natural Heritage Program, Tennessee Valley Authority
Norris, Tennessee 37828-1589, USA

Amphibian species collections and microcassette recordings of anuran vocalizations were made during field work in Bledsoe County, Tennessee, USA. Surveys yielded several new county records that fill gaps in existing ranges or represent range extensions. Lands surveyed lie within the Cumberland Escarpment and Walden Ridge, adjoining the Sequatchie Valley. All collections and recordings were made by WHS. Voucher specimens and recordings were verified by A. Floyd Scott, Department of Biology and Center of Field Biology, Austin Peay State University (APSU). Records for amphibians were considered new if the species in question was not reported from a given county by Redmond and Scott (1996). Nomenclature and common names follow Crother (2000).

Caudata

Ambystoma talpoideum (Mole Salamander). Brushy Pond (35°26'08"N, 85°15'09"W), 12.1 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 16 April 1997. 3 larval specimens (APSU 5587) collected from among submersed and emergent herbaceous and woody vegetation around shallows of 0.2 ha woodland pond. 12 May 1997. 1 larval specimen (APSU 5617) collected from same location and habitat; Laurel Branch (35°24'28"N, 85°16'13"W) 9.8 km E jct. Tennessee Rts. 111 and 28/127, Dunlap. 12 May 1997. One larval specimen (APSU 5606) collected from submerged vegetation and leaf detrital layer in cool, clear, sluggish stream, associated with sphagnum moss wetland in young, hardwood woodland. Horn Branch (35°25'57"N, 85°15'30"W), 11.1 km NE of jct. Tennessee Rts. 111 and 28/127, Dunlap. 12 May 1997. 1 larval specimen (APSU 5613) collected from submersed algal mats and leaf detritus layer of substrate in cool, clear, sluggish stream, associated with sphagnum moss wetland in young hardwood woodland. New county records; represent significant range extension eastward toward Great Appalachian Valley Ecoregion (Tennessee River Valley).

Notophthalmus viridescens viridescens (Red-spotted Newt). Brushy Pond (35°26'08"N, 85°15'09"W, 12.1 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 16 April 1997. 3 larval specimens (APSU 5588) collected from among submersed and emergent herbaceous and woody vegetation around shallows of 0.2 ha woodland pond. 12 May 1997; 3 larval specimens (APSU 5618) collected from same location and habitat. New county record fills gap between adjoining Cumberland, Van Buren, Rhea and Hamilton counties.

Eurycea cirrigera (Southern Two-lined Salamander). Unnamed tributary to McWilliams Creek (35°26'04"N, 85°17'04"), 9.3 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 17 April 1997. 1 specimen (APSU 5593) collected from beneath rotting log associated with leaf litter in hardwood forest, adjacent to stream; downslope from The Big Flat, toward Dry Branch (35°25'25"N, 85°17'05"W), 8.8 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 17 April 1997. 1 specimen (APSU 5596) collected from beneath rotting logs associated with leaf litter in mid-aged hardwood forest; tributary to Laurel Branch (35°24'15"N, 85°15'25"W), 10.8 km E jct. Tennessee Rts. 111 and 28/127 in Dunlap. 12 May 1997. 1 specimen (APSU 5598) collected from beneath rocks in damp stream bed, within hemlock-young hardwood forest; across access road from Brushy Pond (35°26'09"N, 85°15'04"W), 12.2 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 16 April 1997. 1 specimen (APSU 5611) collected from beneath rotting log in saturated soils and leaf litter, in hardwood forest adjacent to headwater stream; unnamed tributary to McWilliams Creek (35°25'39"N, 85°17'44"W), 7.8 km NE jct. Tennessee Rts. 111 and 28/127, Dunlap. 18 April 1997. 1 specimen (APSU 5616) was collected from vertical face of moss-covered, splash-zone of waterfall/rock overhang; Laurel Branch (35°24'18"N, 85°15'33"W), 10.7 km E jct. Tennessee Rts. 111 and 28/127 in Dunlap. 12 May 1997. 1 specimen (APSU 5621) collected from damp area beneath moss-covered rocks comprising man-made wall in woodland adjacent to stream. New county records fill gap between five surrounding counties.

Eurycea longicauda longicauda (Long-tailed Salamander). Dry Branch near Alexander Gap (35°23'38"N, 85°16'35"W), 8.9 km E jct. Tennessee Rts. 111 and 28/127 in Dunlap. 13 May 1997. 1 specimen (APSU 5602) collected from beneath rotting logs and leaf litter in mid-aged hardwood flat along braided stream channel; Laurel Branch (35°24'18"N, 85°15'33"W), 10.7 km E jct. Tennessee Rts. 111 and 28/127 in Dunlap. 12 May 1997. 1 specimen (APSU 5620) collected from damp area beneath moss-covered rocks comprising manmade wall in woodland adjacent to stream. New county records represent eastward range extension toward Great Appalachian Valley Ecoregion (Tennessee River Valley).

Eurycea lucifuga (Cave Salamander). Horn Branch (35°25'57"N, 85°15'30"W), 11.4 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 12 May 1997. 2 larval specimens (APSU 5581) collected from among rootwads and leaf detritus layer of substrate in cool, clear, sluggish stream, associated with sphagnum moss wetland in young hardwood woodland. New county record fills gap among adjoining Cumberland, Van Buren, and Rhea counties.

Hemidactylium scutatum (Four–toed Salamander). Horn Branch (35°25'57"N, 85°15'30"W), 11.2 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 16 April 1997. 1 adult specimen (APSU 5609) collected from within sphagnum moss mat in wetland, adjacent to sluggish stream, in young hardwood woodland. Tennessee listed as *In Need of Management* (Proclamation 94-16). New county record represents eastward range extension toward Great Appalachian Valley Ecoregion (Tennessee River Valley).

Pseudotriton montanus diastictus (Midland Mud Salamander). Across access road from Brushy Pond (35°26'09"N, 85°15'04"W), 12.2 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 16 April 1997. 1 adult specimen (APSU 5610) collected from beneath rotting log in saturated soils and leaf litter, in hardwood forest adjacent to headwater stream; Horn Branch (35°25'57"N, 85°15'30"W), 11.2 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 12 May 1997. 1 larval specimen (APSU 5624) collected from among rootwads and leaf detritus layer of substrate in cool, clear, sluggish stream, associated with sphagnum mass wetland in young hardwood woodland. New county records represent eastward range extension toward Great Appalachian Valley Ecoregion (Tennessee River Valley).

Pseudotriton ruber ruber (Northern Red Salamander). The Big Flat (35°25'27"N, 85°16'38"W), 9.3 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 17 April 1997. 1 specimen (APSU 5595) collected from surface of leaf litter in mid-aged hardwood forest; Dry Branch near Alexander Gap (35°23'38"N, 85°16'35"W), 8.9 km E jct. Tennessee Rts. 111 and 28/127 in Dunlap. 13 May 1997. 2 specimens (APSU 5600) collected from beneath rotting logs and leaf litter in mid-aged hardwood flat along braided stream channel; Horn Branch (35°25'57"N, 85°15'30"W), 11.2 km NE jct. Tennessee Rts. 111 and 28/127 in Dunlap. 16 April 1997. 1 larval specimen (APSU 5608) collected from among rootwads and leaf detritus layer of substrate in cool, clear, sluggish stream, associated with sphagnum moss wetland in young hardwood woodland. 12 May 1997. 1 larval specimen (APSU 5623) collected from same location and habitat. New county records represent eastward range extension toward Great Appalachian Valley Ecoregion (Tennessee River Valley).

Anura

Bufo americanus americanus (Eastern American Toad). Horn Branch (35°25'57"N, 85°15'14"W), 11.3 km NE jct. Tennessee Rts. 111 and 28/127, Dunlap. 16 April 1997. 1 specimen (APSU 5589) buried within sphagnum moss mat in wetland associated with clear, sluggish stream in young hardwood woodland; near Hixon Gap (35°25'48"N, 85°16'09"W), 10.4 km NE jct. Tennessee Rts. 111 and 28/127, Dunlap. 14 May 1997. 1 specimen (APSU 5607) collected from hardwood forest edge and dirt road. New county records fill gap among Cumberland, Van Buren, Rhea, and Hamilton counties.

Acris crepitans crepitans (Eastern Cricket Frog). West of Dry Branch in McWilliams Creek watershed (35°25'28"N, 85°17'35"W), 8.2 km NE jct. Tennessee Rts. 111 and 28/127, Dunlap. 13 May 1997. Microcassette recordings of specimen (APSU 5275) calling from wooded periphery of large, artificial pond. New county record.

The reptilian fauna of Venezuela is becoming taxonomically better known. However, the geographic distribution of many species is poorly known and in need of documentation. In an ongoing effort by the Laboratorio de Biogeografía at the Universidad de Los Andes in Mérida, we provide here 16 new distributional records for Venezuela, one of which is a new species for the country. Twelve of these records are of lizards, while the remainder are those of snakes. Of these new state records, seven come from Carabobo, two each are from Mérida and Yaracuy, with one each from the states of Barinas, Miranda, Sucre, Táchira, and Zulia.

Common names for snakes follow Kornacker (1999), except for those coined recently and not in use by any locals. Common names for lizards are those given by resident people. Acronyms belong to Venezuelan herpetological collections as follows:

CVULA= Colección de Vertebrados de la Universidad de Los Andes, Mérida; CVURG = Colección de Vertebrados de la Universidad Rómulo Gallegos, San Juan de los Morros; ULABG= Colección de Anfibios y Reptiles, Laboratorio de Biogeografía, Universidad de Los Andes, Mérida.

Lacertilia

Ameiva ameiva melanocephala (Mato Real). ESTADO CARABOBO: Municipio Puerto Cabello: Puerto Cabello. 21 April 1994. J. Díaz. ULABG 4124. Verified by P. Kornacker. First state record (Alemán 1953; Donoso-Barros 1968; Peters and Donoso-Barros 1970). ESTADO ZULIA: Municipio: Machiques de Perijá. Serranía de Perijá, river 34 km S El Tukuko, 260 m. elev. 4 March 1985. E. La Marca and J. García. ULABG 1365. Verified by P. Kornacker. First state record and westernmost locality for the subspecies (Donoso- Barros 1968; Peters and Donoso-Barros 1970). Extends range by about 390 km E of previous published record ("La Guayra range"), and 970 km E from type locality (Peters and Donoso-Barros, 1970). This specimen was previously identified as *Ameiva. a. praesignis* in La Marca and García (1987) under the former museum number of CVULA IV-4610.

Anolis squamulatus (Falso Camaleón). ESTADO CARABOBO: Municipio Montalbán: road between Cerro La Pericoca and Temerla. 1000 m. elev., near state border with Yaracuy. 23 March 1999. J. Achuelo. ULABG 4692. Verified by F. Zerpa. First state Record (Donoso-Barros 1968; Peters and Donoso-Barros 1970; extends known range at least 50 km SW of type locality.

Bachia heteropa lineata. ESTADO CARABOBO: Municipio Naguanagua: mountains close to Urbanización La Entrada I, on road to Trincheras, 700 m elev. 25 June 1994. M. Natera and R. Mora. ULABG 4136–4137. Verified by F. Zerpa. These first state records, collected among roots in a evergreen riverine forest at about 100 km SW of the type locality, bridge the previous distribution gap between the state of Yaracuy and the Federal Distrit (Donoso-Barros 1968; Peters and Donoso-Barros 1970).

Gonatodes albogularis albogularis (Limpiacasa). ESTADO BARINAS: Municipio Ezequiel Zamora: Complejo Hidroeléctrico DESURCA C. A., between Santa María de Caparo and Abejales, 23 June 1998. L. F. Esqueda and J. Gámez. ULABG 4418–4424. Verified by F. Zerpa. First records for the state of Barinas and apparently the only documented continental record E of the Cordillera de Mérida. This report extends known range at least 100 km E of Cúcuta, Colombia, the closest geographical locality in the literature (Donoso-Barros 1968; Peters and Donoso-Barros 1970; Rivero-Blanco 1979).

Gonatodes taniae (Largarabo). ESTADO CARABOBO: Municipio Naguanagua: mountains of La Entrada, on road to trincheras, 700 m elev. 25 June 1994. M. Natera and L. F. Esqueda. ULABG 4126–4127. Verified by F. Zerpa. First state records (Donoso-Barros 1968; Peters and Donoso-Barros 1970; Rivero-Blanco 1979). ESTADO YARACUY: Municipio Nirgua: road between Cerro La Pericoca and Temerla. Ca. 1000 m. elev., close to border with state of Carabobo. 23 March 1999. L. F. Esqueda. ULABG 4693. Verified by F. Zerpa. First state record and westernmost locality for the species, extending known range about 90 km W of type locality (Donoso-Barros 1968; Peters and Donoso-Barros 1970; Rivero-Blanco 1979).

Gymnophthalmus speciosus (Falsa Lisa). ESTADO CARABOBO: Municipio Naguanagua: Mountains close to Urbanización La Entrada I, on road to Trincheras, 700 m elev. July 1995. L. F. Esqueda. ULABG 4125. Verified by P. Kornacker. First state record and westernmost locality for the species (Donoso-Barros 1968; Peters and Donoso-Barros 1970; Rivero-Blanco 1979).

Leposoma parietale ESTADO TACHIRA: Municipio Uribante: mountain stream tributary of Doradas river, close to the Uribante-Caparo hidroelectric dam. 24 May 1989. Collector unknown. ULABG 3804. Verified by F. Zerpa. The species was previously known from Peru, Ecuador and Colombia. This is the first record for the species in Venezuela and the northernmost locality for the taxon (Donoso-Barros 1968; Peters and Donoso-Barros 1970; Avila-Pires, 1995). The only other member of the genus previously known for Venezuela was *L. percarinatus* (La Marca 1997).

Plica plica (Cangasapo). ESTADO MIRANDA: Municipio Independencia: Guatopo National Park, sector Agua Blanca. 18 March 1992. M. Natera. ULABG 4134. Verified by P. Kornacker. The specimen, collected on a tree at about 3 m above ground, constitutes the first state record and westernmost northern Venezuelan locality for the species (Donoso-Barros 1968; Peters and Donoso-Barros 1970; Avila-Pires 1979).

Ptychoglossus kugleri. ESTADO CARABOBO: Municipio Naguanagua: Las Trincheras, Las Trincheras river, 500 m elev. 17 August 1993. M. Natera and L. F. Esqueda. ULABG 4148–4149. Verified by F. Zerpa. First state records, bridging distribution gap between states of Falcón and Aragua (Peters and Donoso-Barros 1970; Harris 1994).

Tretioscincus bifasciatus kugleri (Lisa Azul). ESTADO SUCRE: Municipio Montes: Smiths. Hacienda San Fernando. 7 km N Cumanacoa. J. E. García Pérez. 6 August 1985. ULABG 4137. Verified by J. E. García Pérez. First state record (Peters and Donoso Barros, 1970).

Serpentes

Atractus emigdioi (Tierrera). ESTADO MÉRIDA: Municipio Cardenal Quintero: Santo Domingo, near bridge in crossroad to Las Piedras. E. La Marca and D. Briceño. 22 March 1997. ULABG 4335–4336, 4485. Verified by P. Kornacker. First state record for this species, extending known range about 60 km SW of the type locality.

Atractus lancinii (Tierrera). ESTADO CARABOBO: Municipio Naguanagua: Sector Carialinda. S slopes of San Esteban National Park. O. O. Hidalgo. 1994 . CVURG 265. Verified by S. Bolívar. The specimen constitutes the first Carabobo state voucher for this species. This record extends the species range at least 110 km W of the type locality. Since no other museum specimen has been reported in the literature for this taxon, besides the holotype, this specimen, collected on fallen leaves in cloud forest, constitutes the second verified record (Roze 1966). The species range has been stated to include the state of Miranda (Lancini 1979, Lancini and Kornacker 1989), but a voucher specimen is not available at present.

Crotalus durissus cumanensis (Cascabel). ESTADO MÉRIDA: Municipio Libertador: El Morro (Pueblos del Sur), 2000 m. elev. E. Rívas. 25 April 1999. ULABG 4691. Verified by P. Kornacker.

First record for the state and for the Venezuelan Andes. A population of this snake has been regarded as an endangered species, to which the nomen nudum *Crotalus maricela* has been applied (*in* Rodríguez and Rojas Suárez 1995). Close examination of this specimen and others, kept alive, from the same region, suggest that a new name is not warranted, as the scale counts and sizes fall within the range of *C. d. cumanensis* and the pale coloration of some pattern details is common to specimens originating from other semiarid regions in Venezuela. Apparently, this population is restricted to this relatively isolated semiarid pocket in the Venezuelan Andes, ranging from 700 m to at least 2000 m elev. This is one of the highest elevation records for the species (Campbell and Lamar 1989), and the second highest in Venezuela, after a literature citation mentioning it from Pico Naiguatá (Distrito Federal) at 2500 m elev. (Lancini 1979).

Dendrophidion nuchale (Machete). ESTADO CARABOBO: Municipio Guacara: Montañas de Vigirima, on road from El Guapo to Cruz Verde, cloud forest in Southern slope of San Esteban National Park. 25 May 1994. M. Nattera and L. F. Esqueda. ULABG 4143–4144. Verified by P. Kornacker. The specimens, collected by day on the ground, confirm the first state records and northernmost locality for the species, bridging a previous distribution gap of more than 500 km between the states of Zulia and Aragua (Roze 1966, Lancini and Kornacker 1989).

Acknowledgments.—Partial funds were provided to ELM as a co-investigator in the National Geographic Society Grant No. 6176-98 (Herpetofaunal diversity in the lower Andes of Western Venezuela), and the Consejo de Desarrollo Científico CDCHT-ULA Grant No. C-872-97-01-A (Distribución ecológica de la mastofauna y herpetofauna de la región andina. II). The Instituto de Geografía ULA provided a four-wheel vehicle for field research. Rafael Achuelo and the Grupo de Operaciones de Rescates Ofídicos (ORO) provided field assistance. Paul Kornacker reviewed the manuscript and provided helpful comments.

County Records of Amphibians and Reptiles from Northeastern South Carolina

JEFFREY D. CAMPER
Department of Biology, Francis Marion University
Florence, South Carolina 29501-0547, USA
e-mail: jcamper@fmarion.edu

Surveys of locality data from several collections in the United States show that the herpetofauna of northeastern South Carolina is poorly documented. In this report, I list county records for Chesterfield, Darlington, and Florence counties in the northern coastal plain of South Carolina. The taxonomy of *Pseudemys* follows Seidel (1994). All specimens are stored in the Charleston Museum herpetological collection and were collected by the author unless stated otherwise. All specimens were verified by Albert E. Sanders.

Caudata

Amphiuma means (Two-toed Amphiuma). Darlington Co: Pee Dee Research and Education Center, 7 km N Florence. 16 July 1998. CA 4540.

Ambystoma maculatum (Spotted Salamander). Darlington Co: Great Pee Dee River Heritage Preserve, 19.6 km NNE Florence. 25 March 2000. CA 4544. County record and first record on South Carolina coastal plain north of Francis Marion National Forest.

Notophthalmus viridescens (Eastern Newt). Chesterfield Co: Carolina Sandhills National Wildlife Refuge, 1 km NW jct. Refuge Rd. 7 and Co. Rd. 33. 15 October 1995. CA 4408.

Siren lacertina (Greater Siren). Chesterfield Co: Sand Hills State Forest, 3 km SSE State Forest HQ, Flory Pond. 5 July 1995. CA 4407.

Anura

Scaphiopus holbrookii (Eastern Spadefoot). Darlington Co: Hartsville. 3 February 1998. J. W. Bethea. CA 4543.

Hyla chrysoscelis/versicolor (Gray Treefrog). Chesterfield Co: Sand Hills State Forest, 4.2 km S Patrick, Barefoot Seep. 29 June 1995. CA 4402.

Rana sphenocephala (Southern Leopard Frog). Darlington Co: Pee Dee Research and Education Center, 7 km N Florence. 20 October 1998. CA 4542.

Testudines

Chelydra serpentina (Common Snapping Turtle). Florence Co: Florence. 20 March 1998. CR 2699.

Kinosternon baurii (Striped Mud Turtle). Florence Co: Florence, Jeffries Creek. 10 May 2000. J. E. Krebs slide.

Clemmys guttata (Spotted Turtle). Florence Co: 2 km W Francis Marion University on Co. Rd. SSR 918. 22 May 1998. CR 2697.

Pseudemys concinna (Eastern River Cooter). Chesterfield Co: Sand Hills State Forest, 3 km SSE State Forest HQ, Flory Pond. 25 August 1995. T. K. Knowles and J. D. Camper. CR 2698.

Terrapene carolina (Eastern Box Turtle). Chesterfield Co: Sand Hills State Forest, SC Rt. 102 at NW edge of Patrick. 11 June 1995. CR 2587.

Lacertilia

Ophisaurus ventralis (Eastern Glass Lizard). Chesterfield Co: Sand Hills State Forest, 1 km N State Forest HQ on Truck Trail 141.12 June 1995. CR 2583. Darlington Co: 11.3 km NW Florence on Co. Rd. SSR 13. 6 September 1996. CR 2690.

Serpentes

Coluber constrictor (Racer). Darlington Co: South Carolina Rt. 34 within city limits at W edge of Darlington. 3 June 1996. CR 2675.

Elaphe guttata (Corn Snake). Darlington Co: South Carolina Rt. 102, 7.3 km N Hartsville. 28 April 1997. CR 2680. Florence Co: 1.5 km W Francis Marion University on Co. Rd. SSR 918. 31 October 1994. CR 2688.

Elaphe obsoleta (Eastern Rat Snake). Florence Co: 1 km W Francis Marion University on Co. Rd. SSR 918. 22 June 1997. CR 2662.

Farancia abacura (Mud Snake). Darlington Co: Pee Dee Research and Education Center, 7 km N Florence. 3 September 1998. CR 2656.

Heterodon simus (Southern Hog-nosed Snake). Chesterfield Co: Sand Hills State Forest, Co. Rd. SSR 29, 1.2 km S SC Rt. 1. 2 June 1995. CR 2582.

Lampropeltis getula (Common Kingsnake). Florence Co: Quinby. 15 May 1995. L. F. Swails. CR 2647. Darlington Co: Co. Rd. SSR 20 at N edge Hartsville. 6 June 1996. CR 2645.

Masticophis flagellum (Coachwhip). Darlington Co: Co. Rd. SSR 20 at N edge Hartsville. 25 May 1995. CR 2669.

The Central American country of Belize has become a popular ecotourist destination in recent years. This small country (75 x 174 miles [121 x 280 km], 8867 miles^2 [22984 km^2]), slightly smaller than the state of New Hampshire) is located on the southeastern corner of the Yucatán Peninsula south of Mexico, with Guatemala to the west, and the Caribbean to the east. It is a remarkably diverse place for such a small country, ranging from savanna in the north to broadleaf rain forest in the Maya Mountains to the south. The longest barrier reef in the western hemisphere runs along the Belizean coast. Add to this natural history mixture the rich cultural history of the Maya, archaeological treasures like Caracol and Xunantunich, and a diverse ethnic stew of Garifuna, Mestizo, Mayan, Creole, Asian, and European and the appeal of Belize is obvious.

Stafford and Meyers have produced an excellent general guide to the reptiles of Belize. The authors have worked extensively in Belize and their personal knowledge of the country is evident. The authors point out that 75% of the herpetofauna (ca. 160 species) are reptiles, and this volume will be invaluable for anyone with an interest in the reptile fauna of the region. Karl P. Schmidt published the first checklist of the amphibians and reptiles of Belize in 1941; Neill (1965), Henderson and Hoevers (1975), and many others have expanded on this base. Today there are two comprehensive and complementary treatments of the herpetofauna of the region: Julian Lee's 1996 monograph on the herpetofauna of the Yucátan Peninsuala (recently revised and edited as a field guide: Lee 2000) and Jonathan Campbell's 1998 treatment of the amphibians and reptiles of northern Guatemala, the Yucatán, and Belize. In addition to the reptile guidebook by Stafford and Meyer there are currently three shorter, less detailed guidebooks that deal specifically with the Belizean herpetofauna: Garel and Matola (1995) on snakes, Weyer (1990) on snakes, and Meyer and Farneti Foster (1996) on frogs and toads.

The introductory chapter provides a very useful overview of the physiography, climate, and vegetation of Belize with supporting photographs and maps. There is a brief section on general aspects of the natural history of reptiles for the non-herpetologist. This introduction is followed by four chapters devoted to the major reptilian groups (crocodilians, turtles, lizards, and snakes). Dichotomous keys to families, genera, and species are provided for each of these groups (35 keys in all). These keys are supported by high quality drawings by Stafford. General anatomical drawings illustrate basic features of reptilian anatomy and make the keys user-friendly for the novice; unfortunately, the drawings are not specifically referred to in the keys. A glossary of 100 terms further defines anatomical nomenclature and other technical terms. The species accounts are organized in alphabetical order within genera, and the genera are ordered alphabetically within families. Higher taxonomic categories are listed in phylogenetic sequence. Each species account gives the scientific name and original authority, but no nomenclatural history. The common names used by Belizeans for various species are given (some of these are delightful, such as Wish-willy for *Ctenosaura similis*) as well as English and Spanish common names. Each species account includes a description (external morphology, size, coloration), habitat in Belize, geographic distribution, similar species, general remarks (diet, reproduction, recognized subspecies, interesting natural history), and a key reference for each species. The majority of species accounts run about one page of text in length. Species illustrations are included for all but three of the 122 species, and all but six of these are color photographs. There are multiple illustrations for some species and over 180 photographs in all. The last text section of the book is an essay on the features and treatment of snakebite in Belize by David Warrell (Center for Tropical Medicine, Oxford University). There are 13 pages of literature citations and further reading citations. There are four very useful tables in the book. Chapter 1 contains two tables that show the distribution of reptiles in Belize by physiographic region (northern and southern lowlands, and southern uplands) and their distribution in the region (Yucatán, Honduras, Petén). Appendix I is an ecological summary that provides information for each species in nine categories (e.g., habitat, elevational range, food). Appendix II is a table that shows the distribution of each species in each of the seven political districts of Belize. Under each district for each species specific localities are given; a map and gazetteer, including geographic coordinates, are provided.

The species accounts are accurate and well constructed. They contain the traditional description with sufficient detail to confirm identification after a specimen has been tentatively identified with a key. Casual ecotourists will probably never bother with the keys, although they could be used by the patient novice with the aid of the excellent illustrations. The ecotourist will be able to identify all the common species (or at least place a specimen in the correct taxonomic ballpark) using the photographs alone. The photographs are generally of good quality, and many are excellent, in terms of focus and composition; unfortunately a number of the photos are rather dark in terms of the quality of reproduction (at least in my copy) and the animal blends into the background.

Hard-core herpetologists will wish for more information in some cases, especially on the specifics of diet and reproduction. For example, *Ninia sebae*, the Red Coffee Snake, is said (p. 225) to eat invertebrates, which is true. However, it would have been more accurate to say it feeds primarily on gastropods, specifically slugs. In the remarks section of the *Imantodes cenchoa* account (p. 211) the reader is informed that this snake is oviparous. It would not have taken much more space to say that it lays clutches of one to three eggs. Placing this kind of detail in a field guide does not contribute greatly to its length, but it is the kind of information

that increases the utility of the field guide. It makes the details of natural history more accessible to the casual naturalist and stimulates the collection of useful field observations to expand our knowledge of the fauna. This criticism does not detract from the book's usefulness, it simply is a suggestion for future editions and field guide authors everywhere.

One of us (Karns) is a member of a team that teaches tropical biology in Belize and we are always looking for good natural history references for Belize. We will certainly be taking this volume with us in the future. It is a reasonable size for a field guide and the paper and binding are of good quality and durable—it will survive in a backpack. At $59.95 for a paperback we don't think that this book will be bought by the average ecotourist going to Belize, but they will find it a valuable resource if it is available. Individuals with a serious interest in herpetology will find it a very useful introduction to the reptiles of Belize; they will also want more detailed information, analysis, and synthesis than contained here, but there is only so much that a reasonably-sized field guide can do. We hope and strongly recommend that Belizean natural history guides, resort owners who cater to natural history tours, and student group leaders buy and use this book. We work with wonderful natural history guides in Belize who tend to be particularly knowledgeable about birds and medicinal plants, but who are less familiar with other taxonomic groups. In particular, many lizards, like birds, are diurnal, conspicuous, and frequently seen. We think this guide can be very useful in expanding the natural history repertoire of the people who make a living from introducing people to the natural and cultural history of Belize.

This book belongs to the Academic Press Natural World Series and was published in association with the Natural History Museum, London. This series is a new initiative by Academic Press whose goal, according to their press literature, is to produce "...illustrated books dealing with species identification, ecology, and biology. Beautiful books packed with reliable text and illustrations, prepared by experts for the general and dedicated reader alike." They have largely realized that goal with *A Guide to the Reptiles of Belize*.

e-mail: peck@acnatsci.org

One would be hard-pressed to recall many exhibitions—or books—that link the writings of Pliny the Elder and Linnaeus with those of Mark Twain, and Kenneth Grahame, or the scientific offerings of Louis Agassiz with the nonsense verse of Lewis Carroll, but Sally Haines has done just that in *Slithy Toves*. This sumptuous offering of herpetological illustrations and "conversations" about the publications that contain them grew from a 1991 exhibition of books organized by the Kenneth Spencer Research Library at the University of Kansas to celebrate the publication of *A Field Guide to Reptiles and Amphibians* by Roger Conant and Joseph Collins. The exhibition was reconfigured five years later when the Society for the Study of Amphibians and Reptiles met in Lawrence.

Written as a gallery guide to these two exhibitions, the book has the chatty feel of an exhibition tour led by a well-read bibliophile and enthusiastic naturalist who acknowledges at the outset that she is not a specialist in the field of herpetology. In an effort to make her guide more accessible to non-herpetologists, Haines has created her own titles for each of the 69 catalog entries. "Froggie Went a Courtin' " introduces a plate of reproducing frogs from Rosel von Rosenhof's *Historia Naturalis Ranarum Nostratium* (1753–1758), while "We Gott Mit Uns Too" heralds a chameleon plate from an 18th century book by the German naturalist Daniel Meyer. Her other contrived titles include "Crispy Critters," "Reptile Nerds," and "Desert Shield." To give the book a theme and sense of continuity, Haines has also selected a quotation from Lewis Carroll to accompany each bibliographic entry. Like the titles, these tend to trivialize rather than lighten the catalog's content. What seems clever at first, becomes distracting and even annoying when repeated on every page.

Putting aside these extraneous embellishments, the reader will find the book an excellent introduction to the classic illustrated books in herpetology. Although the entries are short—usually no more than a few hundred words devoted to each book—they are filled with useful and interesting information about the eclectic assemblage of authors who created many of the seminal works in the field. (With a few exceptions, books without illustrations were intentionally omitted.)

Kraig Adler, whose groundbreaking work in the history of herpetology is well known to the readers of this journal, served an advisory role to the author of the compilation and contributed a short introduction to the book in which he discusses the artistic challenges of illustrating amphibians and reptiles through time. Following this essay, the book is divided into two chronological

sections and one geographical ("Pre-Linnaean," "Beyond Linnaeus," and "New World Herps"). A section on "Herps as Symbols" constitutes the only non-scientific part of the catalog. The book concludes with chronological and alphabetical checklists of the most important illustrated herpetological works in the Department of Special Collections at the Spencer Library.

Issued in an edition of 1000 by the Society for the Study of Amphibians and Reptiles, *Slithy Toves* is beautifully printed on heavy, coated, acid-free paper. The copious, full-page color reproductions were laser-scanned from 35mm transparencies. Other details about the production are provided in the book's colophon, while a list of patrons and benefactors acknowledges the generosity of those who paid for its publication.

With its unusual contents, its stunning illustrations, and its delightfully readable text, this is a book every natural history book lover and herpetological historian will want to own.

e-mail: aaron.bauer@villanova.edu

Although South America has traditionally been one of the most popular areas for American herpetologists to conduct their fieldwork, the emphasis has decidedly been on Spanish speaking countries. As a consequence of such work, plus the significant output of local herpetologists, the faunas of these countries, as well as that of Portuguese speaking Brazil, are reasonably familiar, if still incompletely known, to herpetologists worldwide. The Guianas of northern South America represent one of the only regions of the mainland Neotropics that is neither Spanish nor Portuguese. The three Guianas (from west to east) were colonized by the British (British Guiana, now Guyana), the Dutch (Suriname), and the French (French Guiana). The herpetofauna of Suriname has been reasonably well documented, largely through the efforts of Marinus Hoogmoed. That of Guyana was explored in the first half of the 20th Century by William Beebe and others, but remains incompletely surveyed and has never been dealt with in book or monographic form. What of French Guiana?

French Guiana remains poorly known to most Americans. Unlike its neighbors, rather than achieving independence, it has become an integral part of France as the largest (approximately 90,000 km^2) of its overseas departments. In that capacity, it has been the site of extensive biological surveys conducted almost exclusively by French researchers. The literature on the amphibians of French Guiana is extensive and much of it has been the work of the senior author, Jean Lescure, who has worked there for more than 30 years. *Atlas des Amphibiens de Guyane*, based on the results of a series of long term investigations sponsored by the Paris Museum and other French research organizations, is, however, the first comprehensive and illustrated publication on the entire batrachofauna of the region.

Following a brief introduction and overview of the methodology of the collecting program that led to the book, a section on the geology, geography and biogeography of French Guiana is presented. In its broader regional context, French Guiana is divided into the central and eastern Guianan regions. On a finer scale, the authors provide a table of distribution that recognizes 14 biogeographic zones within French Guiana, including savannas, coastal marshes, inselbergs, and numerous major river drainages. Despite the extensive survey work of the last 30+ years, there remain several parts of French Guiana that are poorly sampled herpetologically, including parts of the west central region and much of the south (areas where access is poor and infrastructure minimal). In addition to the geographic context of the work, the authors have provided an historical context as well, reviewing 17 naturalists of the past who have contributed to the amphibian biology of the region. These range from Mérian who visited Surinam from 1699 to 1701 to biologists of the early to mid-20th century. Among the more well-known to many herpetologists are Sonnini de Manocourt and Castelnau.

The systematic portion of the book begins with a key to the genera of amphibians. Keys to species within a genus, tribe, or subfamily follow the appropriate general remarks about each higher order group. These often include references to the most recent revisionary systematic works. The keys are, in some cases, illustrated by line drawings and additional illustrations of selected larvae, embryos, pattern variants are scattered throughout the book. Each species account is typically two pages long—one of text and one with a map and photograph. The Latin name, author and date, as well as a French common name head each entry. The accounts themselves are divided into "définition et diagnose," "eco-éthologie," and "répartition." The first of these provides information about size, color and other distinguishing features, the second (which, in some cases, is subsumed under generic accounts rather than specific) includes some aspects of biology as well as information on larval identification and call features. Under "répartition" the distriution of each taxon as a whole is mentioned as is its range within French Guiana. Specific localities are indicated on the adjoining dot maps. These maps show no towns or national or district borders as reference points, only the major river drainages of French Guiana, all of which are identified on a reference map on page 16. An additional "remarques" section in which taxonomic notes, geographic variation, or other topics, are discussed is provided for certain taxa.

Virtually every species is illustrated by a color portrait photograph. These are almost uniformly of good quality, although in a few cases, including several very rare or peripheral species, these are not up to par (e.g., *Atelopus flavescens*, p. 49, image too small; *Colostethus beebei*, p. 85, insufficient depth of field; *Hyla marmorata*, p. 147, poor color reproduction; *Hyla* sp. 1 [identified as *Eleutherodactylus* sp. 1 in the text but corrected in the errata sheet included with the book], p. 217, poor focus; *Synapturanus mirandaribeiroi*, p. 277, preserved specimen).

In total, 103 anuran species and seven caecilians are included in

the fauna. Three of the frogs (*Hyalinobatrachium nouraguensis*, *Hyla guacheri*, *Scinax jolyi*) are described as new. Each of these descriptions provides complete information about the types as well as analysis of calls and other relevant information. Another seven anurans are left unnamed to species, either because they are currently being described by people other than the authors, or because they are insufficiently known. Six species of frogs are added to the fauna of French Guiana and numerous other taxa have been reidentified based on the availablility of new material and/or nomenclatural or phylogenetic revision. These changes are outlined in a one-page English abstract immediately preceding in the index to Latin names.

Five of the seven gymnophione accounts are accompanied by photographs and maps, but these are lacking for *Oscaecilia zweifeli* and *Siphonops annulatus*, both of which are without confirmed precise localities in French Guiana. Here readers may note that the authors have not followed the familial subdivisions of Nussbaum and Wilkinson (1989) that are most commonly adopted in the United States, but have instead used the classification of Lescure et al. (1986), which recognizes the families Oscaeciliidae, Siphonopidae, and Typhlonectidae rather than subsuming these within the Caeciliidae.

A full account (minus map) is also provided for *Adelophryne gutturosa*, which is included as a species of possible occurrence in French Guiana. Text accounts, but no maps or illustrations, are included for *Hyla albomarginata* and *Potomotyphlus kaupii*, which the authors consider to have been erroneously included in the fauna of the country.

The main text concludes with a chapter on amphibian reproductive modes that highlights breeding sites, nest types, developmental patterns and larval strategies, and a notes section providing supplemental information to particular species accounts. A bibliography with more than 225 entries summarizes much of the literature relevant to the amphibians of the Guianas. However, as the authors note, the *Atlas* is not intended as a complete revisionary work, and so the associated literature section is not an exhaustive list of all French Guianan batrachological sources.

Finally, the book concludes with two appendices. The first provides sonograms and tabular summaries of call characteristics (duration, dominant frequency, etc.) for 85 species of frogs. The second provides local names in Creole and a number of other languages in local use in French Guiana. A glossary for the non-specialist defines 45 terms used throughout the text.

The *Atlas des Amphibiens de Guyane* is attractively laid out, with large font size and well-reproduced color photographs, providing large, clear images of each species covered. The book provides a comprehensive introduction to the amphibians of French Guiana and should be considered required for all those working with the amphibian fauna of the Neotropics. Biogeographers and all those interested in the Guianan region as a whole will undoubtedly find the distribution patterns presented of interest and the many herpetologists who are closet historians will certainly appreciate the section on naturalists of the past. The generally very good portraits along with the clear and concise text will provide many herpetologists with their first look at the amphibian fauna of this smallest of South American territories and most exotic of French departments.

The Fourth World Congress of Herpetology will be held 2–9 December 2001, at the Bandernaike Memorial International Conference Hall, Colombo, Sri Lanka. To help colleagues prepare for the trip, we present below a guide to the literature on the herpetofauna of the island of Sri Lanka. This list is not complete, but does include a diversity of English language works including field guides, checklists, and significant taxonomic works relevant to the Sri Lankan herpetofauna. Although most works cited here date from the 20th Century, several important earlier works are also included. A selection of some rarer works, as well as representative newer publications, and books in Sinhalese (dealing chiefly with snake bite and its treatment) will be on display at the Colombo Museum during the Congress. Further information on the Congress can be obtained from the website: www.4wch.com.

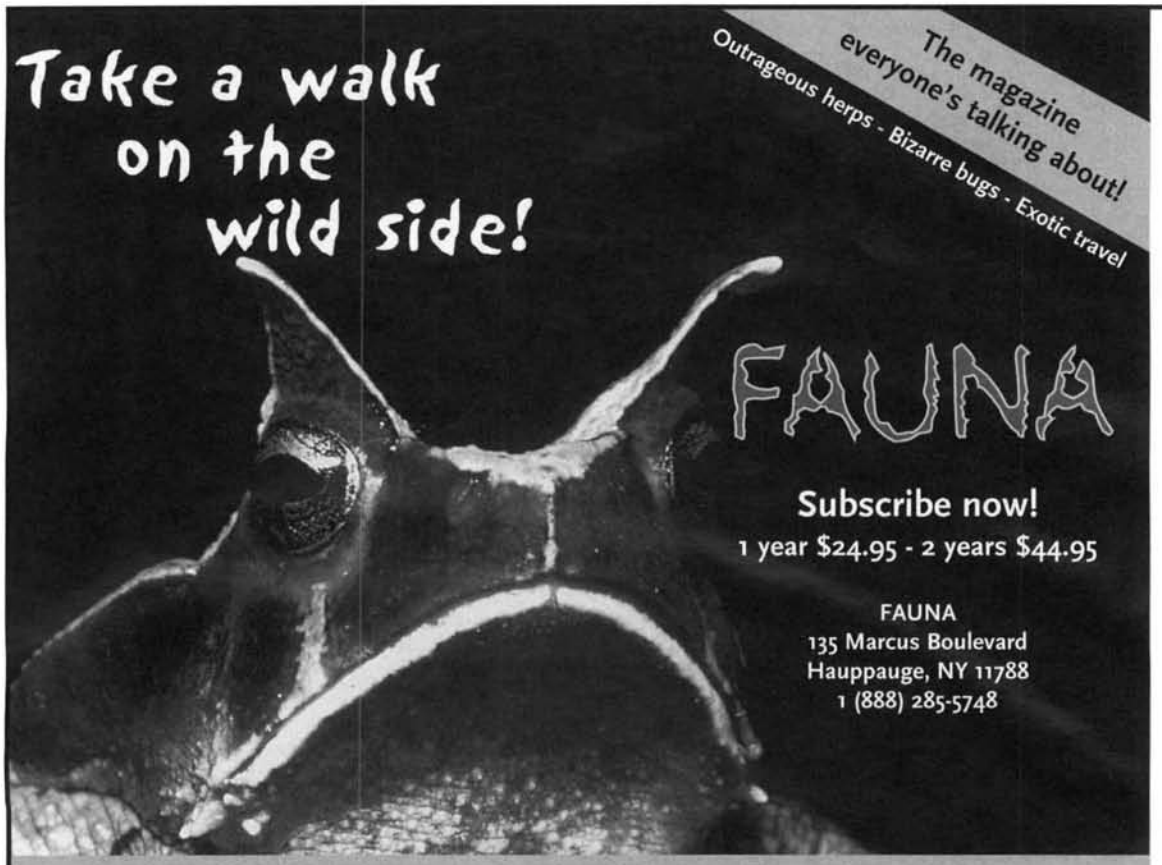
WALL, F. 1921. Ophidia Taprobanica or the Snakes of Ceylon. H. R. Cottle, Government Printer, Colombo. xxii + 581 pp., 1 pl., 1 map. [Reprinted 1993, Navrang Publishers & Booksellers, New Delhi].

For the specialist herpetologist, the following local journals have carried substantial papers on herpetology in the recent past: *Lyriocephalus* (published by the Amphibia and Reptile Research Organisation of Sri Lanka), *Journal of South Asian Natural History* (published by the Wildlife Heritage Trust of Sri Lanka) and *Spolia Zeylanica* (published by the Colombo Museum). Although some works from these journals are listed in the bibliography above, many additional papers (including numerous species descriptions) of herpetological relevance have appeared in these periodicals. Additional Sri Lankan references may be found in *Journal of the Bombay Natural History Society* and a diversity of regional and international journals of herpetology, zoology, natural history, and conservation.



PUBLICATIONS RECEIVED

The Amphibians and Reptiles of Alberta: A Field Guide and Primer of Boreal Herpetology, 2nd edition, by Anthony P. Russell and Aaron M. Bauer. 2000. University of Calgary Press, 2500 University Drive NW, Calgary, AB, Canada T2N 1N4. xii + 279 pp. Softcover. CAN$ 24.95 (approx. US $16.50) plus shipping.

This is a revised version of the 1993 book on the Albertan herpetofauna. In only seven years, five of the 18 species in the province have undergone name changes in association with taxonomic revisions. In addition to a revised bibliography and point locality maps, the new edition features updates to most of the text and new information about the status of amphibians and reptiles in Alberta. Numerous black and white drawings and photographs have been improved from the first edition and the color plates include a number of new images by wildlife photographer Wayne Lynch.

Hybridization Among Western Whiptail Lizards (*Cnemidophorus tigris*) in Southwestern New Mexico: Population Genetics, Morphology, and Ecology in Three Contact Zones, by Herbert C. Dessauer, Charles J. Cole, and Carol R. Townsend. 2000. Bulletin of the American Museum of Natural History 246. 148 pp. US $14.00.

This monograph examines hybridization between *Cnemidophorus tigris punctilineatus* of the Sonoran Desert and *C. t. marmoratus* of the Chihuahuan Desert along a contact zone in the Animas Valley of New Mexico. Data from mtDNA, alleles, and morphology indicate that hybridization occurs across a steep, relatively narrow step-cline that is probably the result of secondary contact following the most recent reconnection of the Sonoran and Chihuahuan Deserts within the last 5000 years. There appear to be no differences in fitness across the hybrid zone. The hybrid zones are described and illustrated in great detail, serving as a baseline for future studies of the contact between the two taxa. The research presented has broader relevance for the understanding of the evolution of parthenogenetic forms of hybrid origin, some of which are derived from *C. tigris*. Overall, this publication makes a significant contribution to the study of the complex picture of the biology and evolution of North American *Cnemidophorus*.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, and Legislation & Conservation should be sent directly to the appropriate section editor. Send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, Herpetological History, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without consulting the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 700	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@slu.edu.

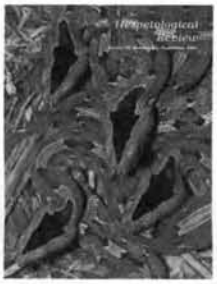
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.



ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2001 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2002 — Crown Center Hotel, Kansas City, Missouri, USA. 3–8 July 2002 (with ASIH, HL)

About Our Cover: *Bitis nasicornis*

Characterized by rather stout bodies and heavily keeled scales, the snakes of the genus *Bitis* are among the most spectacular viperids. Ranging from the Arabian peninsula to southern Africa, 14 species are currently recognized (McDiarmid et al. 1999. Snake Species of the World: A Taxonomic and Geographic Reference. Vol. 1. The Herpetologists League, Washington, D.C. 511 pp.). Considerable size variation exists among *Bitis* species. The largest member of the group, the Gaboon Viper (*Bitis gabonica*), reaches lengths of over two meters and weights exceeding 10 kg (Pitman 1974. A Guide to the Snakes of Uganda. Revised ed. Wheldon & Wesley, Codicote, England. 290 pp.). The Namaqua Dwarf Adder (*Bitis schneideri*), the smallest adder in the world, averages just 20–25 cm in total length (Spawls and Branch 1995. The Dangerous Snakes of Africa. Ralph Curtis Books, Sanibel Island, Florida. 192 pp.).

Bitis nasicornis, known as the Rhinoceros Viper due to the horn-like appendages decorating its snout, is one of the more strikingly-patterned forms. Recent phylogenetic analysis based upon mitochondrial DNA sequences corresponds with immunological and morphological evidence in suggesting that it is closely related to *Bitis gabonica*, but not to the other large species within the genus (Lenk et al. 2001. Molecular Phylogenetics and Evolution 19:94–104).

Essentially a denizen of equatorial forest, the Rhinoceros Viper earned the name of 'River Jack' by early naturalists for its affinity for water. This impressive snake also appears to inhabit the dense undergrowth around farms and plantations where its cryptic pattern and colors allow it to remain effectively hidden. The function of the modified rostral projections on its snout is unknown, but may aid in crypsis. Primarily terrestrial in habits, specimens have been found in trees. Climbing however, can present a potential physiological problem for such a large, stout-bodied snake. Larger specimens of *Bitis* are unable to maintain minimal levels of carotid blood flow when tilted at angles exceeding 30°. Fully erect vertical positions cannot be maintained for very long periods without experiencing problems associated with syncope and pulmonary edema (Lillywhite and Smits 1992. *In* J. A. Campbell and E. D. Brodie, Jr. [eds.], Biology of the Pitvipers, pp. 143–154. Selva, Tyler, Texas).

The Rhinoceros Viper is actively hunted in Africa as an important source of protein. In Nigeria, Luiselli et al. (1998. Amphibia-Reptilia 19:223–229) found it was frequently traded in bushmeat markets as food and as "totems" in animistic religious cults. Occasionally featured as "bushmeat of the day" in some restaurants in Cameroon, the Rhinoceros Viper also appears to be used in a dried form by locals as a preventative against snake bite in the field (Lawson 1993. Herpetol. Nat. Hist. 1[2]:27–90).

The 25–28 cm long juvenile *Bitis nasicornis* depicted on the cover were photographed by **R. Michael Burger** at the San Antonio Zoo in 1998. Michael's intent was to capture the symmetry created by the four javelin-shaped cephalic markings against the complexity of the interwoven dorsal patterns, resulting in a directional flow in the photograph. The equipment used in obtaining the image included a Nikon 401x camera with a Sigma 90 mm f2.8 macro lens, a Nikon SB-23 flash, and Fujichrome Provia film. "Seeing the image and actually capturing it on film are sometimes two entirely different things," Michael freely admits, "though *Bitis nasicornis* tend to make good photographic subjects due to their sedentary nature." A member of Dallas Zoo's Department of Herpetology, his pen-and-ink drawings, photography, and articles have appeared in a variety of U.S. and European publications, including *Herpetological Review*. Michael is shown here photographing a *Norops* species at Caño Palma Biological Station near Tortuguero, Costa Rica.

Separation and imaging of Burger's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

NEWSNOTES

Sociedad Herpetológica Mexicana

The Sociedad Herpetológica Mexicana (SHM) is a non-governmental organization founded in 1988. The main objectives of the SHM are the interchange of ideas, attempts to increase knowledge of amphibians and reptiles, and provide communication among herpetologists and other biologists interested in the herpetofauna of Mexico through its publications (SHM *Bulletin*) and biannual meeting. Accordingly, SHM welcomes the donation of relevant books, reprints, or other herp-related materials that would further these aims. Donated materials can be sent directly to: *Aurelio Ramírez Bautista, SHM President, Lab. de Ecología, UBIPRO, FES-Iztacala, UNAM, Av. de los Barrios s/n, Los Reyes Iztacala, Tlalnepantla, Edo. de México. C.P. 54090, Mexico; e-mail: raurelio@servidor.unam.mx.*

Annual dues are US $30.00 for persons outside of Mexico (this includes delivery costs for the SHM *Bulletin*), and $ 150.00 pesos ($ 75.00 pesos for students) (MN) for residents of Mexico. To become a SHM member, please contact: *M. en C. Guadalupe Gutiérrez-Mayén, SHM Treasurer, Universidad Autónoma de Puebla, Escuela de Biología, Edif. 76, Ciudad Universitaria, 75570 Puebla, Puebla, Mexico; e-mail: mggitier@siu.buap.mx.*

For additional information about the SHM, please visit their website (in Spanish): http://www.ecosur.mx/shm/pagshm.htm.

MEETINGS

Current Research on Herpetofauna of the Sonoran Desert II 5–7 April 2002

The Tucson Herpetological Society (THS) and co-sponsors announce the second meeting of *Current Research on Herpetofauna of the Sonoran Desert* (CRHSD II), to be held at the Four Points by Sheraton Tucson University Plaza, Tucson, Arizona, 5–7 April 2002. The goals of this meeting are twofold: 1) dissemination of information concerning research on the herpetofauna of the Sonoran Desert, the States of Arizona and Sonora, and the Baja California peninsula and associated islands, and 2) the social interaction of everyone attending the meeting. There will be a Friday evening Icebreaker Social, Scientific Sessions on Saturday and Sunday, and a Saturday evening Banquet. Invited speakers are Daniel D. Beck and Harry W. Greene.

Information on the CRHSD II meeting is available on the THS web site <http://tucsonherpsociety.org> and from Roger Repp (tel. 520-318-8210, e-mail: rrepp@noao.edu) or David L. Hardy Sr. (tel. 520-624-8879, e-mail: dhardysr@theriver.com).

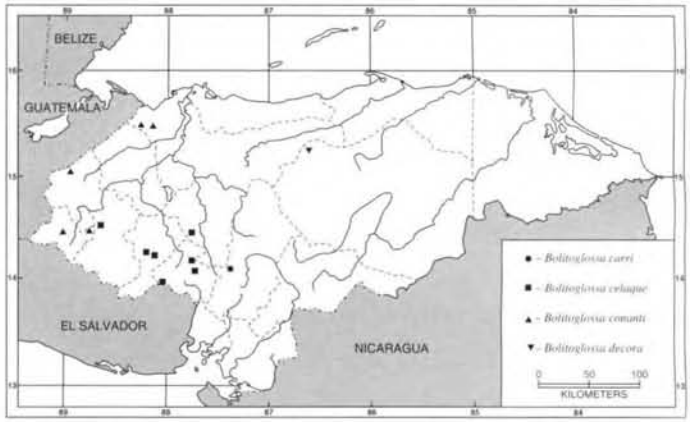
Another New Book from the Society for the Study of Amphibians and Reptiles

THE AMPHIBIANS OF HONDURAS

by James R. McCranie and Larry David Wilson

The first complete treatment of the amphibians of any Mesoamerican country . . . . The present work, a product of 15 years of labor, will surely stand as a model in tropical herpetology for completeness, accuracy, attention to detail, and scholarship . . . . A major contribution to our knowledge of Central American herpetology. — JAY M. SAVAGE, from the Foreword.

HONDURAS IS THE SECOND LARGEST OF THE seven Central American countries. Its amphibian fauna, however, has been the least known in the region and numerous studies have referred to the "Honduran hiatus" in distribution and in our understanding of the systematics of indigenous species. The authors, James R. McCranie and Larry David Wilson, who began field work in Honduras in 1976 and 1967, respectively, have made an intensive study of the amphibian fauna and have now produced a



book that will serve to make the amphibian fauna of Honduras one of the best known in the world. They have spent a total of more than 1500 days in the field and have personal field experience with nearly every species. They have examined more than 9500 adult specimens and about 500 lots of tadpoles and egg clutches in researching this book. The result is a model faunal study that will be a welcome reference for scientists and conservationists alike. It will be a reminder of the potential loss of biodiversity in a country in which deforestation and loss of habitat have greatly accelerated over the last decade.

The Honduran amphibian fauna consists of 116 species of caecilians (2 species), salamanders (25), and frogs (89), including members of nine families: Caeciliidae (2), Plethodontidae (25), Bufonidae (8), Centrolenidae (8), Hylidae (31), Leptodactylidae (33), Microhylidae (3), Ranidae (5), and Rhinophrynidae (1). The book has ex-

tensively illustrated identification keys, a discussion of reproductive modes and ecomorphological guilds, distribution, and essays about the human impact on, and future of, the Honduran amphibian fauna. The bulk of the book consists of detailed accounts of the species (each one includes synonymy, range, diagnosis, description of adult [and tadpole where applicable], references to published illustrations, remarks, ecological distribution, natural history, etymology, and specimens examined).

There is a gazetteer of Honduran localities, a glossary, a comprehensive literature cited section, and indexes to authors and taxa. Finally, there are **20 COLOR PLATES** including 24 photographs of habitats and 130 of amphibians.

Map 5. Localities for four species of the Bolitoglossa dunni *group.*

Specifications: about 400 pages, 7 x 10 inches, 123 maps and figures, 33 tables, 20 color plates, clothbound. ISBN 0–916984–57–5. To be published December 2001.

PRICES: Pre-publication to SSAR members US$50; Institutions and non-members US$60. *SHIPPING:* USA address, add US$4; non-USA, US$8

SEND ORDERS TO: Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103–2010, USA (*telephone:* area code 314–977–3916 or 977–1710; *fax:* 314–977–3658; *e-mail:* ssar@slu.edu). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may also be charged to MasterCard or VISA (please provide the account number and card expiration date). SSAR membership information and a complete list of all Society publications can be obtained on request to Dr. Aldridge.

Meetings Calendar

2–4 November 2001—28th Annual Meeting, Kansas Herpetological Society, Topeka, Kansas, USA. http://eagle.cc.ukans.edu/~cnaar/khs/AnnualMeetingInfo.html.

2–9 December 2001—Fourth World Congress of Herpetology, Colombo, Sri Lanka. Details from: 4WCH Promotions Office, 95 Cotta Road, Colombo 8, Sri Lanka; e-mail: admin@4wch.com; http://www.4wch.com.

5–7 April 2002—Current Research on Herpetofauna of the Sonoran Desert II, Tucson, Arizona, USA. http://tucsonherpsociety.org.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Influence of Antipredator Defenses in the Distribution of Amphibian Prey Species

Species distributions can be influenced by prey antipredator defenses. After a three-year study at the Reserva Florestal Adolfo Ducke in Brazilian Amazonia, Hero et al. described how defenses against predators influence the composition of a tadpole assemblage. The predators analyzed were the fish *Pyrrhulina* sp. and the dragonfly naiad *Gynacantha membranalis*. Unpalatability, an effective defense mechanism of tadpoles against one of the predators (fish), was found to influence the composition of tadpole assemblages within bodies of water. Because unpalatability is not effective against all predators, it is the heterogeneous distribution of fish and insect predators among bodies of water that increases prey species diversity at the community level. Thus, antipredator defenses and predator distribution influence alpha and beta diversity of this anuran community.

Hero, J.-M., W. E. Magnusson, C. F. Rocha, and C. P. Catterall. 2001. Antipredator defenses influence the distribution of amphibian prey species in the central Amazon rain forest. Biotropica 33(1):131–141.

Prepollex and Prehallux Variation in Anurans

Most anurans have a prepollex and prehallux. Fabrezi investigated the variation of these poorly studied structures in more than 100 species of anurans and analyzed their ontogeny in some neotropical species. The author found that the morphological diversity of the prepollex and prehallux is based on the number and characteristics of the distal elements of these structures. Ontogenetic analysis revealed that the prepollex and prehallux differentiate in a proximo-distal sequence, distal to Element Y. Fabrezi also presents further evidence for non-homology between these structures and true digits. The most widespread morphology of the prepollex/prehallux corresponds to two distinct elements, of which the distal one is more or less developed. Several unrelated species of anurans have well-developed distal elements, which apparently have defined ecological roles. The occurrence of the prepollex and prehallux in other lissamphibians and extinct groups needs to be investigated in order to interpret these structures in the evolution of tetrapod limbs.

Fabrezi, M. 2001. A survey of prepollex and prehallux variation in anuran limbs. Zoological Journal of the Linnean Society 131:227–248.

A New Fossil Caecilian from Africa

The oldest known fossil caecilian is *Eocaecilia* from the Lower Jurassic Kayenta Formation of western Arizona. The authors describe the second oldest fossil of the group from a Lower Cretaceous microfossil locality in the eastern High Atlas Mountains, Morocco. *Rubricacaecilia monbaroni* is described from elements of the mandible, as well as several vertebrae, a palatine, and a possible limb bone. Based on the length of the lower jaw, the authors estimate that the specimen was about 20 cm long. *R. monbaroni* differs from all known caecilians, living and fossil, in several osteological features, one of the most interesting being the retention of a tuberculum interglenoideum on the atlas. The tuberculum interglenoideum is absent in all other caecilians except the fossil *Eocaecilia*; among living amphibians it is present in salamanders only. *Rubricacaecilia* has a unique combination of osteological characters, which place it between *Eocaecilia* and more derived caecilians. The authors conclude that, among Gymnophiona, *Rubricacaecilia* is the most basal taxon after *Eocaecilia*. Whether *Rubricacaecilia* represents the morphological stage of Gondwanan caecilians at the Lower Cretaceous cannot be answered without additional material.

Evans, S., and D. Sigogneau-Russell. 2001. A stem-group caecilian (Lissamphibia: Gymnophiona) from the Lower Cretaceous of north Africa. Palaeontology 44(2):259–273.

Response of Red-sided Garter Snakes to Pheromones

Pheromones are among the chemical signals used by many animals for orientation. Some snakes make pheromone trails in order to guide conspecifics to the location of potential mates or location of winter hibernacula. The authors investigated the conspecific trailing behavior of *Thamnophis sirtalis parietalis* in a natural environment by carrying out two field experiments within the Interlake region of Manitoba, Canada. The experiments were performed during the breeding season and the period of migration. The authors tested the response of both sexes to conspecific pheromone trails. It was found that only adult males use pheromone trails for locating potential mates. Neither males nor females used the pheromone trails for location of winter hibernacula, which contradicts previous laboratory-based studies. However, this discrepancy might be due to differences in experimental design. In addition, the authors found a significant trend for females to avoid male pheromone trails near the hibernacula during the period of migration. This suggests that females tend to escape male courtship at the winter hibernacula. Trail avoidance behavior is something that requires further study.

LeMaster, M. P., I. T. Moore, and R. T. Mason. 2001. Conspecific trailing behaviour of red-sided garter snakes, *Thamnophis sirtalis parietalis*, in the natural environment. Animal Behaviour 61:827–833.

Lung-inflation Mechanisms of an Agamid Lizard

Traditional views have stated that amniotes utilize aspiratory pumping as their sole means of breathing. However, recent studies in varanids have demonstrated that lizards can expand the lungs via gular pumping. In order to elucidate the pattern of breathing in agamid lizards, 14 *Uromastyx aegypticus* were collected in Saudi Arabia; electromyogram, electrocardiogram, and plethysmography data were collected. The primary mode of breathing was a triphasic lung inflation and deflation involving the intercostal muscles. When the lizards were prodded or experienced temperatures above 30°C the buccal pump was utilized. This alternate form of breathing involves the sphincter colli and the geniohyoid muscles. The two forms of breathing never occurred simultaneously; buccal pumping invariably followed thoracic breathing after the second expiration. The authors demonstrated that the buccal pump was controlled by a Hering-Breuer reflex. Although it is tempting to classify the buccal pump as a structure with a respiratory role, the authors caution that more research is necessary to confirm this hypothesis.

Al-Ghamdi, M. S. A. D., J. F. X. Jones, and E. W. Taylor. 2001. Evidence of a functional role in lung inflation for the buccal pump in the agamid lizard *Uromastyx aegypticus microlepis*. Journal of Experimental Biology 204:521–531.

Amphibian Colonization of Restored Wetlands

The great loss of wetlands in the United States has led to restoration projects in an attempt to provide habitat for native wetland biota. The authors studied colonization of seven restored wetlands in southern Minnesota by pond-breeding amphibians. The restored wetlands were former agricultural fields or located in an urban area. Chorusing and visual encounter surveys as well as larval sampling were performed to find amphibians in these wetlands. Distance to source ponds, restored wetland size, and dispersal abilities were significant predictors of species richness, whereas restored wetland age and distance to forest patches were not. Four species of amphibians—*Rana clamitans, Pseudacris crucifer, Ambystoma laterale,* and *Notophthalmus viridescens*—occurring in adjacent, unimpacted wetlands, were not found in restored wetlands. The importance of isolation and patch size in restored wetlands supports the idea that many amphibian populations have a metapopulation structure caused by low vagility, philopatry, and patchy breeding habitat. The authors demonstrated that restored wetlands provide adequate habitat for at least some species of pond-breeding amphibians and suggest that factors such as spatial isolation and habitat suitability should be considered in wetland restoration projects.

Lehtinen, R. M., and S. M. Galatowitsch. 2001. Colonization of restored wetlands by amphibians in Minnesota. American Midland Naturalist 145(2):388–396.

The Midblastula Transition Prevents Apoptosis in *Xenopus* Embryos

Ionizing radiation administered to *Xenopus* embryos results in DNA damage and apoptosis before, but not after, the midblastula transition (MBT). The authors investigated the molecular mechanisms responsible for the prevention of apoptosis after the MBT. Phosphorylation experiments indicated that the serine/threonine kinase Akt (or protein kinase B) may participate in the antiapoptotic signaling pathway of embryos irradiated after the MBT. Constitutively active Akt delayed apoptosis in embryos irradiated before the MBT but did not completely prevent apoptosis from occurring. Results also indicated that two gene products (Bax and Bcl-2) interact to prevent apoptosis after the MBT. Moreover, the cdk inhibitor $p27^{Xic1}$ can arrest cells in the G_1 phase (post-MBT) or bind with cyclin complexes to arrest cells at the G_1/S transition. Apoptosis is prevented after the MBT by the coordinated efforts of these components.

Finkelstein, C. V., A. L. Lewellyn, and J. L. Maller. 2001. The midblastula transition in *Xenopus* embryos activates multiple pathways to prevent apoptosis in response to DNA damage. Proceedings of the National Academy of Sciences 98:1006–1011.

Family Structure in an Australian Scincid Lizard

Previous studies have documented the existence of stable family groups in lizards, but none have utilized genetic markers to document the relationship of the members. The authors examined genotypes of six microsatellite loci in a stable group of *Egernia stokesii* from South Australia. Average relatedness was calculated with RELATEDNESS 5.04, genetic distance between pairs of groups was calculated with MICROSAT, and a Mantel test (GENEPOP v3.16) tested for correlations between dispersal of groups and geographic distance. The average relatedness among all lizards of the study was –0.0106; relatedness was not significantly different among members of either sex. Relatedness data indicated that parents and offspring belonged to the same social group in most cases. Average within-group relatedness among the sexes suggested that these lizards have sex-biased dispersal, with males dispersing from social groups more often than females. However, all adults showed a tendency to associate with related individuals. Mantel tests indicated that individuals tended to disperse to proximate groups more often than distant groups—however this correlation was noted as weak. Although the relatedness of members of each group was high, individuals tended to seek out mates that were unrelated. Kin recognition may help these lizards to avoid inbreeding.

GARDNER, M. G., C. M. BULL, S. J. B. COOPER, AND G. A. DUFFIELD. 2001. Genetic evidence for a family structure in stable social aggregations of the Australian lizard *Egernia stokesii*. Molecular Ecology 10:175–183.

Predation on Frogs and Lizards in a Panamanian Humid Forest

Many trophic relationships of tropical ecosystems are poorly documented, especially predator-prey interactions. The authors studied bird predation on frogs and lizards in a Panamanian humid forest to assess whether: 1) bird species that prey upon vertebrates are larger or more social (when foraging) than those species that do not eat vertebrates; 2) a decrease in arthropod prey will increase the likelihood of eating vertebrate prey; 3) frog-eating species are more selective in their prey choice compared to lizard-eating species. Birds were captured over a 13 month period with mist nets in 8 transects (35 m apart), forced to regurgitate prey items, banded, and released. Relative abundance of frogs and lizards was estimated from diurnal censuses; arthropod abundance was estimated from sweep-net samples in close proximity to the mist net sites. Forward stepwise-computed multiple logistic and linear regression analyses were used to identify vertebrate-eating bird species and factors accounting for frog or lizard intake over time.

Based on regurgitates, birds preyed upon *Anolis*, *Ameiva*, and *Eleutherodactylus*—but not on *Colostethus* and *Bufo* which were the two most common anuran genera. The probability of predation upon lizards was highest when birds followed army-ant swarms; predation on frogs was best explained by the variables of bill length and body length of birds. Breeding activity and arthropod abundance explained seasonal variation in lizard predation; seasonal variation in frog predation was explained by frog abundance.

POULIN, B., G. LEFEBVRE, R. IBÁÑEZ, C. JARAMILLO, C. HERNÁNDEZ, AND A. S. RAND. 2001. Avian predation upon lizards and frogs in a neotropical forest understory. Journal of Tropical Ecology 17:21–40.

Effects of UV-B Radiation on Diet of Bufonid Tadpoles

Depletion of the ozone layer can lead to increased levels of UV-B radiation and deleterious effects to freshwater ecosystems. The authors tested the effects of UV-B radiation on phytoplankton and its resulting nutritional value to *Bufo boreas* tadpoles. Algae were grown on microscope slides at four localities in Colorado; tadpoles were collected from each locality. Periphyton was grown in glass boxes with mylar-covered, acetate-covered, or open tops to allow different levels of UV-B radiation to enter each box. In general, as altitude increased, protein concentration decreased and chlorophyll concentration increased. Although density of algae did not differ among the treatment groups, the composition of taxonomic groups varied. Open treatment samples were not significantly different from tadpole gut contents. Because tadpoles were not selectively feeding, the nutritional quality of available algae may have affected the development and fitness of these tadpoles.

ROGERS, K., A. SCHMIDT, J. WILKINSON, AND T. MERZ. 2001. Effects of incident UV-B radiation on periphyton in four alpine freshwater ecosystems in central Colorado: impacts on boreal toad tadpoles (*Bufo boreas*). Journal of Freshwater Ecology 16:283–301.

Costs of Predator-induced Phenotypes in Ranid Tadpoles

Tadpoles raised in the presence of predators often develop adaptive phenotypes, but the costs of these phenotypes are difficult to quantify. The authors examined the performance of tadpoles with predator-induced phenotypes during and immediately after metamorphosis. Tadpoles of *Rana ridibunda* were raised in outdoor tanks with either no predators or a single late-instar dragonfly larvae confined to a cage. Tadpoles were collected 37 and 46 days after hatching, photographed in lateral and ventral views, and returned to the tanks. These photographs were used to obtain measurements of the tadpoles. Once the tadpoles displayed forelimbs, they were removed from the tanks to facilitate daily measurements and estimate development rate. Froglets were allowed to hop on a flat table to measure hopping performance before preservation in 10% formalin. Results indicated that the morphology of tadpoles differed between treatments, and froglets from the caged-predator tanks developed through metamorphosis slightly faster than the control group. Although froglets from the caged-predator tanks

had short and muscular legs compared to those from tanks without predators, hopping performances did not differ significantly between treatment groups.

VAN BUSKIRK, J., AND G. SAXER. 2001. Delayed costs of an induced defense in tadpoles? Morphology, hopping, and development rate at metamorphosis. Evolution 55:821–829.

Egg Activation of the Newt, *Cynops pyrrhogaster*

An increase of intracellular Ca^{2+} levels triggered from fertilizing sperm can activate eggs in many groups of animals. However, an artificial increase of 1,4,5-trisphosphate (IP_3) levels can induce a transient increase of intracellular Ca^{2+} levels as well. The authors studied factors leading to increased intracellular Ca^{2+} levels in the newt, *Cynops pyrrhogaster*. Sperm extract was obtained from adult male newts and injected into adult female eggs. Intra-

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 2002 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include *in situ* behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

6. INTERNATIONAL. Proposals may address needs in any of the above five categories, but applicants must be from countries where herpetological research has historically been underfunded, and where alternative sources of financial support are scarce or nonexistent.

7. BIBLIOGRAPHIC RESEARCH. This special category continues for 2002 thanks to a donation from Itzchak and Carolyn Gilboa. Proposals should address a major need to consult library or other information resources. The project must focus on a herpetological topic. Proposals from individuals only, accompanied by a letter of support from someone knowledgeable about the applicant and about the importance of the project.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be students AND members of the SSAR with the exception of those applying for support of regional herpetological society projects, or those applying in the international category. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 2001 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. Past recipients of an SSAR GIH award in any category are not eligible for future awards. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) TITLE PAGE giving the title of the project, the name, mailing address, office and home telephone numbers and, if possible, fax number and e-mail address of the applicant. The title page should include a statement indicating that applicants "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects." (B) BACKGROUND AND OBJECTIVES of the proposed project. (C) METHODS of carrying out the project. (D) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). Include an explicit explanation of how an SSAR award of $500 would be applied toward the objectives of the project, and provide a listing of all current and pending support for the project. (E) BRIEF RESUMÉ of the applicant or project coordinator. (F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed 1200 words, excluding title page, literature cited, resumé, and budget. Applicants must indicate word count on their application.

Applicants must designate to which of the seven categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than **31 DECEMBER 2001** to be considered. Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced on or around 1 April 2002. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Erik R. Wild, Chair, SSAR Grants-in-Herpetology, Department of Biology, University of Wisconsin - Stevens Point, Stevens Point, Wisconsin 54481-3897, USA. Tel. (715) 346-4269; Fax (715) 346-3624; e-mail: ewild@uwsp.edu.*

cellular Ca^{2+} levels, Ca^{2+} waves, cyclin B1, and BrdU incorporation into DNA was measured. Results indicated that a proteinaceous factor from sperm cytoplasm had the ability to activate eggs via a transient increase in intracellular Ca^{2+} levels. Increased levels of intracellular Ca^{2+} was also caused by the injection of IP3, but ryanodine receptors did not cause a similar effect. It is not yet clear if the sperm cytoplasmic factor is the primary cause of egg activation in newts.

ORIGINAL WATERCOLOR PAINTINGS BY DAVID M. DENNIS

from

Duellman's "Hylid Frogs of Middle America"
(2001 edition by SSAR)

SSAR is offering for sale the unique original watercolor paintings from which the color plates in Duellman's "Hylid Frogs of Middle America" (2001 edition) were reproduced. These range in price from US $100 to $500 and are individually signed by the artist.

A price list is available on request to the SSAR Publications Secretary, Dr. Robert D. Aldridge, address: Department of Biology, Saint Louis University, 3507 Laclede, Room 127, Saint Louis, Missouri 63103, USA; e-mail: ssar@slu.edu; fax: 314–977–3658; phone: 314–977–3900.

Field Identification of Chytridiomycosis in *Rana muscosa* (Camp 1915)

VANCE T. VREDENBURG
and
ADAM P. SUMMERS
Museum of Vertebrate Zoology, University of California
Berkeley, California 94720, USA
e-mail (VTV): vancev@socrates.berkeley.edu

A chytrid fungus, *Batrachochytrium dendrobatidis*, causes the deterioration of the keratinized mouthparts of tadpoles (Nichols et al. 2001), and has been implicated in amphibian declines in Australia, the Neotropics, and in Europe (Berger et al. 1998; Bosch et al. 2001). The fungus is widespread, and has been identified on six continents: Africa, South America, Central America, North America, Europe, and Australia (Speare and Berger 2000). In California, chytrids have been identified in nine amphibian taxa (*Rana muscosa*, *Rana aurora draytonii*, *Rana aurora aurora*, *Rana boylii*, *Rana catesbeiana*, *Bufo canorus*, *Hyla regilla*, *Spea hammondii*, and *Ambystoma macrodactylum croceum*; Fellers et al., *in press*); however, it is not known whether they are the cause of population declines. Because the fungus grows on keratinized tadpole mouthparts, we believe field assessment of tadpole populations, and the

collection of voucher specimens, will be an important tool in determining the extent and severity of chytrid infection. This should be particularly easy in frogs with large tadpoles such as the mountain yellow-legged frog, *R. muscosa* (Vredenburg et al., *in press*). The symptoms of chytridiomycosis include loss of black pigment from jaw sheaths and tooth rows within 1–3 weeks of infection (Fellers et al., *in press*).

The photograph above shows *R. muscosa* with two potential stages of chytridiomycosis infection b), and c) and one apparently uninfected animal a). The arrow indicates the lower jaw sheath in all three photos. Notice that a) has complete tooth rows and dark jaw sheaths while b) is lacking dark tooth rows and has only a thin dark line on the jaw sheaths. In c) the beak and tooth rows are completely colorless. Tadpole a) was collected in 1976 near Sonora Pass, Alpine County, California, USA (MVZ 137435). Tadpoles b), and c) were collected near Ebbetts Pass, 2 June 2001, Alpine County, California, USA (MVZ, not accessioned). Tadpoles b) and c) are being histologically analyzed. Recently, however, J. Longcore (pers. comm.) cultivated a *Batrachochytrium* fungus from *R. muscosa* in the Sierra Nevada and we expect these will also contain the fungus.

We ask that any herpetologists encountering tadpoles in the Sierra Nevada pay careful attention to tadpole mouthparts and report any occurrences to the authors (e-mail: vancev@socrates.berkeley.edu). If proper permits are attained, a single voucher should be placed in 95% ethanol and sent to the primary author. We will maintain a website with information on the chytrid situation in the Sierra Nevada:

This note lists corrections for the most recent list of scientific and standard English names of North American amphibians and reptiles north of Mexico (Crother et al. 2000). To avoid future problems, please mark these corrections on your list.

ANURA

p. 7: *Bufo boreas boreas* Baird and Girard should be dated 1852, not 1853.

pp. 7–8: *Bufo velatus* is placed in both the synonymy of *Bufo fowleri* and as a subspecies of *Bufo woodhousii*. This is in error although the correct placement of the name is inherently controversial. Sullivan, Malmos, and Given, 1996, Copeia, 1996: 274-280, noted that nominal *velatus* sits within the hybrid zone of *Bufo fowleri* and *Bufo woodhousii*, and at this time should not be recognized.

p. 8 *Bufo valliceps*: Populations in the USA and northeastern Mexico should now be called *Bufo nebulifer* according to Mulcahy and Mendelson (2000, Mol. Phylogenet. Evol. 17:173).

p. 10, 2nd line. *Pternohyla* listed twice.

p. 15 *R. sphenocephala*: Change "leaving the unusual situation where the subspecies name *utricularia* has priority over the younger species name *sphenocephala*" to "leaving the unusual situation where the younger species name *sphenocephala* has nomenclatural priority over the older subspecies name *utricularia*."

p. 15 *Rana virgatipes*: Change "Cryptic species are not expected" to "Data presented by Pytel, Herpetologica 42(3):273, suggest that careful evaluation for cryptic species are warranted."

SAURIA

p. 34 *C. arizonae*: Insert "Lowe" (before "op. cit.") at the end of the last sentence of the note. The citation should read "Wright and Lowe (op. cit.)."

p. 35 *C. h. beldingi*: Insert a space after "Grismer" at the beginning of the last sentence of the note.

p. 38 *C. t. stejnegeri*: In the last sentence, delete "endemic" after "*C. t. multiscutatus*" and insert it after "insular." The sentence should read: "Following Maslin and Walker (1981), we have treated *C. t. multiscutatus* (type locality: Isla Cedros, Baja California) as the name of an insular endemic and *C. t. stejnegeri* (type locality: Ensenada, Baja California) as the name of the subspecies occurring in coastal southern California."

p. 49 *Phyllodactylus*: LEAFTOED GECKOS (without a hyphen) should read LEAF-TOED GECKOS (with a hyphen).

p. 53 *S. a. argus*: Insert "by" after "was not reported" in the note. The passage should read: "the subspecific identification was not reported by them but was given..."

p. 54 *S. n. notatus*: Insert "1858" (in parentheses) after "1859" (not in parentheses).

p. 54 *U. microscutatus*: Delete the terminal "s" in "Small-scaled lizards."

SERPENTES

p. 64 *L. g. nigra*: *niger* should be spelled *nigra*.

p. 67 *N. s. sipedon*: Common Watersnake should read Northern Watersnake.

p. 69 *R. braminus*: Insert "b" in front of *raminus*. Should be spelled *R. braminus*.

CROCODILIA

p. 74 *Alligator*: *mississipiensis* should be spelled with two p's: *mississippiensis*.

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 2001, with notification by 1 December 2001. Grantees are expected to complete their Academy visit by 15 September 2002. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

New Localities and Natural History Notes on *Bipes canaliculatus* in Guerrero, México

WENDY L. HODGES
Section of Integrative Biology, School of Biological Sciences
University of Texas at Austin, Austin, Texas, 78712-1064, USA
e-mail: camaleones@mail.utexas.edu

and

EDMUNDO PEREZ-RAMOS
Museo de Zoología, Facultad de Ciencias, Universidad Autónoma de México
A.P. 70-399, México D. F., 04510, México
e-mail: epra@hp.fciencias.unam.mx

The genus *Bipes* consists of three species endemic to Mexico. *Bipes canaliculatus* occurs in the states of Guerrero and Michoacán, *B. tridactylus* is only known from a small coastal region of Guerrero, and *B. biporus* occurs on the Baja Peninsula (Alvarez 1964, 1966; Flores-Villela 1993; Papenfuss 1982; Smith and Taylor 1950). *Bipes* are generally found in moist, sandy soils of arroyos, coastal and alluvial plains of river basins, in agricultural or pastoral fields adjacent to rivers, or under or around bushes in sandy areas (Alvarez 1966; Gadow 1905; Papenfuss 1982). One account by Smith (1949) describes how he and E. H. Taylor found *B. canaliculatus* under large, weathered sandstone rocks characteristic of exposed slopes of arroyos. He suggested *B. canaliculatus* might be found more frequently under rocks after heavy rains; however, all other researchers have reported finding them by digging in sandy river soil. While the taxonomy and systematics of *Bipes* has been established (Gans 1967; Papenfuss 1982), the natural history of all *Bipes* remains poorly known despite intensive efforts by Papenfuss (1982). This note describes the discovery of *B. canaliculatus* in new localities and in different microhabitats than previous researchers.

We searched for reptiles and amphibians by turning over large stones and dead trees or breaking logs apart at two localities north of the Río Balsas (also known as Río Mexcala) from 17 to 22 November 1998. The Río Balsas is a large river that flows through central Guerrero, México, and separates the Sierra Madre del Sur from the Cordillera Volcanica. Localities where we searched and found *B. canaliculatus* were recorded using a GPS unit. One locality is across the Río Balsas, north of Tlalcozotitlan, and east of Hueyatl (17°53'38"N, 99°07'28"W, 540–580 m). The second locality is Atzcala, 14 km west of the old Highway 95 crossing at the Río Balsas (17°58'41"N, 99°39'50"W) and 2–3 km north of the river (Fig. 1). Data collected on most specimens at the instance of capture included date, time, habitat description, and body, air, and substrate temperatures (Table 1). All temperatures were recorded with a cloacal thermometer within 0.1°C. Twelve specimens were deposited in the Museo de Zoología Facultad de Ciencias (MZFC 11523–11534) and four live individuals were donated to the herpetarium at the Universidad Nacional Autónoma de México (all died and were later deposited in the MZFC collections, MZFC 11674–11675 and MZFC 12924–12925).

FIG. 1. Previously recorded (solid circles) and new (triangles) localities for *Bipes canaliculatus*.

We collected sixteen *B. canaliculatus* from Guerrero. The two localities where we collected *B. canaliculatus* add to the seven sites where the species has been previously recorded (Fig. 1). The locality near Hueyatl extends the recorded range of *B. canaliculatus* approximately 35 km east. Atzcala is also a new locality but lies between previously known sites along the Río Balsas.

Seven specimens were found near Hueyatl 1–2 km north of the river. Five individuals were found under large rocks on gravel slopes, not sand. One individual was found in an old, dry, rotten *Bursera* sp. trunk, and one individual was found under an unidentified rotted trunk. General habitat consisted of mesquite covered hills separated by flat plains used for seasonal agriculture. Residents at this locality said they often encountered *B. canaliculatus* in their fields while plowing or working. Residents referred to the animals as "culebras con manitas," (snakes with little hands), "culebras con dos patas," (snakes with two feet), and "tlalcocoanetl," (a name in the Nahuatl language).

We found nine *B. canaliculatus* north of Atzcala. Eight were found under large rocks on steep slopes, and one individual was found in a rotten log. The habitat on the hillsides is sparse arid scrub forest and relatively pristine, while the lower valleys are completely cultivated. The altitude of the Río Balsas directly south of Atzcala is approximately 460 m, and we collected specimens up to 810 m in elevation. The specimen collected furthest from the river was located just north of the coordinates 17°59'10"N and 99°39'59"W, which is 3–4 km north of the Río Balsas.

The soil immediately under rocks where we found all the *B. canaliculatus* was hard and coarse, not like the sandy soils near the river. Individuals had burrows that led to the surface of the ground under rocks. They escaped down holes once the rocks were lifted if they were not captured quickly. Once in their burrows, they were difficult to extract because well-developed claws on their forelegs firmly grasp the sides of their tunnels and help pull them under ground.

We extended the known range of *B. canaliculatus* east 35 km, but no one has yet reported collecting them from the state of Puebla, the northeastern limits of the Balsas basin. While we added two new localities to known sites where *B. canaliculatus* occurs, these localities confirm previous suggestions that the species occurs throughout the Río Balsas Basin (Alvarez 1966; Papenfuss 1982; Smith and Smith 1977).

We found *B. canaliculatus* in rocky soils and coarse gravel on hillsides and steep slopes over three kilometers away from the Río Balsas. We also found them in rotten logs. Gadow (1905) considered *B. canaliculatus* to be "bound to sandy soils." Papenfuss (1982) collected the majority of his specimens by paying local residents to dig in the soft soils along the bank of the Río Balsas and in arroyos and fields near the river. He described his study site at Petacalco as having sandy soil interspersed with extensive areas of coarse gravel, but it is not explicit whether he found them in coarse gravel or only in sandy areas. Smith's (1949) experience was similar to ours in that he found *B. canaliculatus* more distant from the river on a hillside and under rocks, but the soils were still described as sandy (Smith and Smith 1977). Ours is the first record where *B. canaliculatus* was found over three kilometers from the river in coarse gravel to rocky soils and inside old, dry, rotten logs. The Atzcala location is particularly interesting because specimens were found high on steep hills in deciduous vegetation, a very different habitat than previously described for the species. Other amphisbaenians are found commonly in upland rocky terrain or forested habitats (Beebe 1945; Gans 1962; Gans and Alexander 1962: Vanzolini 1951).

Our data suggest *B. canaliculatus* can also be found to a much greater extent during the wet season in forested habitats under rocks or in logs without the necessity of digging. Smith (1949) also suggested *B. canaliculatus* might be found under rocks more often during or after the wet season. Localities where we found *B. canaliculatus* have a distinct wet season in the summer and a prolonged dry season lasting five to six months (Flores-Villela 1993). In the Summer and Fall of 1998, extremely heavy rains fell throughout México, especially in southern states. The rains had subsided by November when we were collecting, but the previous

TABLE 1. Recorded Capture Data. Date, time, habitat description, and substrate ($T_{substrate}$), body (T_{body}) and air (T_{air}) temperatures at time of capture for *Bipes canaliculatus* specimens. NA means Not Available: Temperatures were not recorded when handling for a long period of time before obtaining a good reading, or if the microhabitat was destroyed before a specimen was discovered. For example, rotten logs were usually completely broken apart before individuals were encountered. WLH had the thermometer; if EPR collected an individual when separated from WLH, temperature data were not recorded.

Date Collected	Time Collected	Habitat Description	T_{body} (°C)	$T_{substrate}$ (°C)	T_{air} (°C)
Site 1					
17 Nov 1998	1100	Under large rock in gravelly soil, ca. 1 km N of the river on small hillside, 580–600 m	34.2	35.0	33.0
17 Nov 1998	1709	Inside rotten *Bursera*, ca. 2 km N of the river on tall hillsides	32.4	29.3	31.5
18 Nov 1998	1223	Under rock in gravel and dirt on the eastern slope of tall hillsides ca. 2 km from river	NA	30.0	32.8
18 Nov 1998	1423	Under rock in loose dirt, western slope of taller hillsides, ca. 2.25 km from river, 700 m	34.8	26.0	NA
18 Nov 1998	1730	Under a rock, 730 m	NA	NA	NA
19 Nov 1998	1013	In the soil under a dry rotten log on hillsides to the east, 640 m	34.4	29.8	30.6
19 Nov 1998	1535	Under a large rock, 20 cm below the surface of the ground, 640 m	33.0	30.6	37.0
Site 2					
20 Nov 1998	1540	Rocky hillside surrounding Atzcala, 564 m	NA	NA	NA
20 Nov 1998	1711	Inside a dry, old rotten log on the rocky hillsides ESE of Atzcala, 800 m	NA	NA	28.6
21 Nov 1998	1055	Under rock in soft dirt on brushy hillsides to the north of Atzcala	35.2	32.3	34.4
21 Nov 1998	1618	Under a rock in soft dirt, several km north of Atzcala in woodland	32.4	27.4	28.2
22 Nov 1998	1210	Under a rock, steep slopes, several km N of Atzcala in woodland (17°59'10"N, 99°39'59"W, 710 m)	28.6	27.2	32.2
22 Nov 1998	1220	30 m from specimen above, but rock was in the sun	32.0	31.2	32.2
22 Nov 1998	1245	+100 m N of the previous specimens, under a rock with loose soil, steep slopes	32.2	29.6	32.4
22 Nov 1998	1245	Under the same rock as above specimen	33.8	29.6	32.4
22 Nov 1998	1345	N of previous specimens, rocky habitat, closer to the top of a steep hill, 810 m	NA	NA	NA

months' rain may have facilitated our finding the species in unknown habitats more distant from the Río Balsas. This species, and perhaps all *Bipes*, may be much more common and widespread but simply not visible except during the wet season.

In two instances, we found *B. canaliculatus* inside old, dry, rotten *Bursera* sp. trunks, and in one instance, an individual was found underneath an unidentified rotten log. These records are the first reports of finding *B. canaliculatus* inside or associated with rotten logs. Additionally, they were less than one meter from ant nests inside the same logs suggesting they may have been feeding on the ants, larvae, or pupae. Several *Amphisbaena* species have also been found in close association with ants (Beebe 1945; Gans 1962; Gans and Alexander 1962).

Papenfuss (1982) gathered over 900 *B. canaliculatus* specimens from local residents, but only a few (N = 36) had body temperature and substrate temperature data or burrow characteristics where specimens were collected. Papenfuss recorded a mean burrow depth of 19.8 cm, ranging from 2.5 cm to 60 cm. All specimens we collected were in the soil at depths less than 20 cm, which was the measured depth of the largest rock under which a *B. canaliculatus* was found. Our body and substrate data agree with Papenfuss' data: body temperatures were significantly higher ($p < 0.004$) than substrate temperatures for our collected specimens. We also extended thermal data over a longer daily time period compared to Papenfuss (1982).

Bipes canaliculatus was rare in museums until Papenfuss (1982) discovered they could be collected in large numbers by digging in sandy banks and alluvial soils of the Río Balsas. We discovered this species could also be found under rocks on steep slopes and hillsides out of the primary Río Balsas channel. We also discovered them associated with rotten tree trunks and ant colonies, microhabitats previously unknown for *B. canaliculatus*. Increased understanding of this unique reptile's ecology may be acquired by shifting collecting efforts from digging in sandy river banks to searching the hillsides during the rainy seasons of southern México.

Acknowledgments.—This research was supported by a Continuing University Fellowship to WLH by the University of Texas at Austin. Collecting was done under Permit No. FAUT-0015 extended to EPR. Special thanks to A. Nieto Montes de Oca for assisting WLH with obtaining the initial Mexican collecting permit (DOO.750.-5300) that allowed us to take this trip and O. Flores-Villela and M. Benabib who provided additional permits, support, and assistance in Mexico City. Special thanks to the family of A. Adame who let us use one of their buildings as a base camp during the Atzcala portion of our work. Thanks to M. Cardoso, A. Gluesenkamp, C. Guthrie, L. Ramakrishnan, M. Swartz, and two reviewers for comments on this manuscript.

In California, overwintering tadpoles have been reported for only two ranid species: *Rana muscosa* (mountain yellow-legged frog) (Stebbins 1985) and *R. catesbeiana* (bullfrog) (Behler and King 1979; Leonard et al. 1993). Storer (1925) states that *R. aurora* spend 4–5 months as larvae with metamorphosis typically taking place between July and September. We report here our observations of *Rana aurora draytonii* (California red-legged frog) tadpoles overwintering at 11 sites spread over four counties in central coastal California. We define overwintering as spending the winter (November–February) in the larval stage (≤ Gosner stage 40; Gosner 1960).

One site is located in a spring-fed pool that drains into Matadero Creek (Santa Clara Co., 37°24', 122°10', 200 m elevation). On Mar 20, 1998 we caught two distinct size classes of tadpoles, five small individuals (approximately 30 mm TL), and two large ones (72 mm and 92 mm TL; Gosner stages 36 and 38 respectively). There was also a recently metamorphosed *R. aurora* (28 mm SVL). On Oct 15, 1999 we found a tadpole with only rudimentary hind limbs (Gosner 36). The pool measured 3 x 5 m and was >1.0 m deep. It was heavily shaded with California blackberry (*Rubus ursinus*), willow (*Salix* sp.), and poison oak (*Toxicodendron diversilobum*).

On Nov 3, 1999 a 65 mm tadpole was caught at one of several pools along a 150 m stretch of Round Valley Creek (Contra Costa Co., 37°52', 121°46', 128 m elevation). The tadpole had only small hind limb buds (Gosner 32). On Dec 15, 1999 an additional three tadpoles (Gosner 36–37) were captured in the same creek, and on Jan 7, 2000 one Gosner stage 39 tadpole was found. The creek ran through an oak savannah woodland, which was seasonally grazed by cattle. Two of the pools were >1.0 meter deep including the one where the tadpole was captured. Prior observations indicate that tadpoles have overwintered at this site each year since 1997. Recent metamorphs have been found in April, much too early to be young of that year because eggs are typically laid at this site during March. During winter storms, the creek carries a substantial amount of water and rises as much as a vertical meter, at least for short periods of time. It is not clear how *R. aurora* tadpoles survive these events.

Four ponds in the Kellogg Creek drainage (Contra Costa Co., 37°47', 121°43', 323 m elevation) have been observed to have *R. aurora* tadpoles during the late fall and winter for each of the last two years. On Nov 5, 1998, 287 tadpoles were caught at an artificial stock pond located in a heavily-grazed grassland. The tad-

poles ranged in size from 19 to 37 mm SVL, and from 39 to 75 mm TL. None of these tadpoles had hind limbs or hind limb buds (< Gosner 26). Subsequent surveys conducted at this pond demonstrated that tadpoles were present well into the winter (Nov 3, 1999 [3 tadpoles, 83–87 mm, Gosner 38–40]; Feb 8, 2000 [3 tadpoles]; and Feb 12, 2000 [1 tadpole]). Three other ponds in the Kellogg Creek drainage were surveyed in early 1999 (37°48', 121°43', 220–277 m elevation), and overwintering tadpoles were captured on the following dates: Jan 21 (14 tadpoles, < Gosner 37), Feb 12 (9 tadpoles, < Gosner 37), and Mar 3 (12 tadpoles, < Gosner 37). All four of the ponds were located in a heavily-grazed grassland with no trees within 1 km.

On Apr 6, 2000 a pond in Morgan Territory (Contra Costa Co., 37°49', 121°48', 607 m elevation) was surveyed and found to have three overwintering tadpoles (Gosner 45).

On Nov 10, 1999 three tadpoles (72 mm, Gosner stages 34–37) were found in a pond near Abbotts Lagoon (Marin Co., 38°7', 122°56', 24 m elevation). The pond was 75 x 10 m, and > 1.0 m in depth. It was surrounded by introduced Mediterranean grasses, while rushes (*Juncus* sp.), sedges (*Carex* sp.), and marsh pennywort (*Hydrocotyle verticillata*) grew in or near the water.

On Jan 16, 2000 tadpoles were seen at Guadalupe Dunes (San Luis Obispo Co., 34°59', 120°38', 37 m elevation) during a nocturnal survey. Ten overwintering tadpoles were captured that ranged from Gosner stage 25 to 42. All tadpoles appeared to be well nourished and healthy. One additional tadpole (stage 37) was captured at a second, nearby pond on Jan 22, 2000. Both ponds were 35–45 cm deep with water temperature of about 15°C. The shores of both ponds were heavily trampled by cattle, and the aquatic vegetation was browsed. These ponds were located only 400 m from the Pacific Ocean.

Sixteen overwintering tadpoles (Gosner stages 25–40) were found at a second locality in San Luis Obispo County (35°27' 120°55', 10 m elevation) on Jan 23, 2000. These tadpoles were in an arroyo about 1 km southeast of the mouth of Villa Creek, north of Cayucos. All the tadpoles were in a 1 x 2-m plunge-pool that was about 70 cm deep and shaded by a willow tree and two-meter high steep banks. The pool was located about 50 m from the ocean in a heavily-grazed grassland dominated by introduced Mediterranean grasses.

We suspect that overwintering is not common in larval *R. aurora*. We were able to find overwintering *R. aurora* tadpoles at only one of six known breeding sites in Marin County and at only two of seven sites in San Luis Obispo County. California's Mediterranean climate may influence the timing of oviposition (winter) and metamorphosis (summer/fall) in *R. a. draytonii*. High-flow events during winter are normal in California creeks, and undoubtedly provide strong selection pressure for 1) frogs to delay egg-laying, and 2) larvae to complete metamorphosis before winter storms. Eggs laid before March in coastal creeks in San Luis Obispo County have been washed away by late winter storms (GR, pers. obs.). Similarly, tadpoles that do not metamorphose before early winter storms risk being lost. Hence, overwintering in *R. a. draytonii* does not appear to be highly adaptive, especially for populations that breed in streams.

Overwintering in *Rana a. draytonii* is probably closely related to water temperature, an important factor in determining the rate of tadpole development (Altig and McDiarmid 1999). We would expect to encounter overwintering tadpoles most frequently in high-altitude regions where the warm summer season is short; in aquatic areas with deep shade that prevents solar radiation from warming the water; and along the narrow coastal strip where cold ocean temperatures, prevailing wind, and summer fog create cool summer conditions. Unusually cool summers, as brought about by La Niña ocean cooling, may exacerbate local influences on summer temperatures. *Rana a. draytonii* tadpoles at all the sites described above were living in ponds, pools, or parts of streams that appear to be cooler than is typical for this species. We are currently monitoring temperature at several sites to evaluate whether temperature is likely to be a contributing factor.

Our observations of overwintering *R. a. draytonii* tadpoles are important in part because this frog is Federally-listed and the US Fish and Wildlife Service is in the process of revising guidelines for conducting formal surveys. Our findings indicate that in some areas, surveys for both tadpoles and recent metamorphs may need to be conducted over a much longer period of time since the length of the larval period can range from 4 (Storer 1925) to 13 months (this study).

Acknowledgments.—We thank Patrick Kleeman, Leslie Long, Randy Schmeider, and Julie Schneider for assistance with field work and Joan Fellers for useful comments and discussion on the manuscript. Field work was funded by the USGS Western Ecological Research Center and UNOCAL. Collecting permits were provided by the National Park Service, California Department of Fish and Game, and the U.S. Fish and Wildlife Service.

A Novel Behavior for Urodeles: Micturition in the Plethodontid Salamander *Aneides lugubris*

Micturition, the release of fluid from the bladder, is well known to occur when some species of frogs and toads are handled. Although this behavior is generally considered an antipredatory tactic—it presumably startles the predator and gives the potential prey item additional seconds to escape—there are few data supporting this claim (Buchanan and Taylor 1996; Duellman and Trueb 1986). In one of the few studies to test the advantages of micturition, Buchanan and Taylor (1996) found that squirrel treefrogs (*Hyla squirella*) that emptied their bladders before jumping, jumped significantly farther than frogs that had not emptied their bladders. This result suggests that a function of micturition in frogs is to decrease the frog's weight to enable a more efficient escape.

Micturition during handling has not been previously documented for salamanders. We document this behavior for the arboreal salamander, *Aneides lugubris* (Plethodontidae).

Nine adult *A. lugubris* (6 female, 3 male) were tested weekly for the micturition response (Set 1: 4 animals, 8 trials/animal between September and November 1996; Set 2: 4 animals, 18 trials/animal between March and July 1999; 1 animal: 6 trials between June and July, 1999). The salamanders were collected in Alameda County, California, USA, and were individually housed in 18.5 x 7.5 x 9 cm containers lined with moist paper towels. Temperature was maintained at 15°C with a 12:12 h light:dark cycle. Salamanders were fed crickets *ad libitum*. All applicable institutional animal care guidelines were followed.

For Set 1, a micturition trial involved lifting each salamander out of its container and holding it over a collecting tray lined with plastic wrap. For maximum visibility of the vent region, animals were lifted vertically with the experimenter's gloved hand above and the fingers loosely encircling the animal. Liquid that dripped off the animal and potentially came from the salamander's vent was saved and its pH measured. A sample of water from the salamander's container was collected at the same time and its pH measured as well. Samples were collected using a micropipetter and stored in scintillation vials.

For animals in Set 1, a pH test and a food coloring test were used to distinguish between urine and water from the salamander's container that may have been on the salamander but dripped off during handling. The pH of container water and potential urine samples was measured using the acid-base indicator, phenol red, which turns from yellow to red over the pH range of 6.6–8.0. For the food coloring test, green food coloring was added to the containers of two *A. lugubris* three days prior to a micturition test. The color of the potential urine samples collected when the salamanders were handled was then visually compared to an equivalent volume of the green container water under similar conditions (e.g., lighting, background). We predicted that if we were observing micturition, the color of the potential urine sample would be clear and not green.

For Set 2, animals were lifted and observed for micturition as in Set 1, but no liquid samples were collected. We used a conservative method for scoring micturition. Liquid dripping from the animal was recorded as micturition only if it was released suddenly and came unambiguously from the vent region.

Results support the hypothesis that arboreal salamanders micturate when handled. From the four initial test animals (Set 1), 15 potential micturition events were observed (liquid dripped off salamander in the vent region), 13 samples were successfully collected, and 11 of these turned distinctly red (basic pH) when tested with phenol red. In contrast, all samples of water from salamander containers, collected at the same time as the potential micturition events, turned yellowish-red (neutral pH) when tested. Two of the samples collected from the salamanders did not have a basic pH and thus were not scored as micturition events. Each of the salamanders of Set 1 micturated at least twice during the 8-trial testing period (average number of micturition events per salamander was 2.8; range 2–4). Micturition occurred a minimum of 34% of the time salamanders were handled (11 micturition events/32 trials). The average volume of the collected samples was 154 ± 79.3 ul (range 50–380 ul). It was not evident that any salamander micturated more or less frequently at the beginning or end of the testing period; the salamanders apparently did not habituate to handling.

For the food-coloring test, samples collected from the handled salamanders were clear compared to the green solution from the salamander containers. This result supports the results from the pH tests that the samples collected from the salamanders were not simply water from the salamander containers. Visual observations corroborate results from the pH analyses and the food coloring tests that both male and female *A. lugubris* micturate. When an animal is handled, occasionally there is a sudden release of liquid and the experimenter's hand is suddenly quite wet.

Using our conservative estimate of scoring micturition events, each salamander in Set 2 micturated at least once (6% of the time; range 1–2) during the testing period although liquid dripped off the animals in the region of the vent up to 30% of the time.

Our results show that micturition occurs under laboratory conditions in *A. lugubris*. Each of the nine individuals tested micturated at least once in response to handling. Individuals of *A. lugubris* show this behavior in the field as well (NLS, pers. obs.). Anecdotal reports of micturition in other species of *Aneides* (*A. hardii*, NLS, pers. obs.) and in other plethodontid genera (*Plethodon cinereus*, S. Wise, pers. comm.; *Pseudoeurycea*, *Chiropterotriton*, G. Parra, pers. comm.) suggest that this behavior may be widespread at least among terrestrial plethodontid salamanders. Additional work is necessary to demonstrate the functional significance, if any, of this response. Salamanders exhibit a wide variety of antipredatory strategies such as irritating skin secretions, running, writhing, biting, tail autotomy, toxin-tipped ribs, vocalizations, immobility, and crypsis (Arnold 1982; Brodie 1977, 1978; Brodie

et al. 1974; Brodie et al. 1989; Ducey and Brodie 1983; Nowak and Brodie 1978). Micturition is another potential strategy to include in this diverse set of antipredatory behaviors for salamanders.

Losing the bladder contents may be of significant consequence for a salamander in a water-stressed environment. Frogs that use their bladders to store water are better able to avoid desiccation in water-limited environments than frogs that do not store water (Feder and Burggren 1992; Ruibal 1962). Thus, under certain environmental conditions, micturition may compromise a salamander's survival.

Acknowledgments.—We thank NSF (IBN 9506781 to NLS) for partial support, the California Department of Fish and Game for permission to collect *A. lugubris* (permit # 4755), B. Buchanan, H. Lefcort, S. Marks, and anonymous reviewers for comments, and R. Bello for assistance with collecting and salamander care.

Proposed Deletion of Two Colubrid Snakes from the Mexican State of Durango Herpetofauna

ROBERT G. WEBB

Laboratory for Environmental Biology and Department of Biological Sciences
The University of Texas at El Paso, El Paso, Texas 79968-0519, USA
e-mail: rgwebb@utep.edu

Coluber constrictor.—Wilson (1966) first reported *C. constrictor* in Durango in referring the Mexican specimens to *C. c. oaxaca*. The status of the one Durango specimen (juvenile, ca. 260+186 mm) was appraised by Smith (1971) as seemingly referable to *C. c. oaxaca*, but by Greene (1983) as sharing features with other subspecies.

Collection data for the Durango specimen (Field Mus. Nat. Hist. 1503) is Coyotes, Sierra Madre, 8000 ft, obtained by Heller and Barber, August 1904; an attached metal tag is etched with the number 482. Smith (1939:31) noted this same museum number (FMNH 1503) assigned to a lot of seven specimens (now FMNH 218615–21) of *Thamnophis macrostemma megalops* (= *T. eques*) with the same collection data. Heller and Barber did visit the Coyotes area of Durango and collect several specimens of other species (FMNH), but they also visited the states of Coahuila, Vera Cruz, Puebla, and Oaxaca in eastern Mexico in 1904 (Smith 1939).

Smith (1971) cast doubt on the occurrence of *Coluber constrictor* on the Pacific slopes of Mexico. Wilson's (1978) map localities are lacking in western Mexico, except for the Coyotes, Durango locale. Heller and Barber's juvenile *C. constrictor* (FMNH 1503) was likely included with the specimens collected from Coyotes, Durango instead of with specimens from one of the aforementioned states in eastern Mexico. A substantial amount of field work by me and colleagues in the Coyotes area in the intervening years, aided by access via paved Highway 40, has not revealed additional specimens of *C. constrictor*. Pending the acquisition of additional geographically pertinent specimens the occurrence of *C. constrictor* in Durango is dismissed.

Conophis vittatus.—Wellman (1963:281, Fig. 5) mapped the northernmost record of *C. vittatus* on the Pacific coast of Mexico in extreme southern Durango (close to Nayarit border) based on Amer. Mus. Nat. Hist. specimen R14217 from "Hacienda de Gabriel." This one and only Durango specimen, ca. 198+56 mm with about 154 ventrals and 74 subcaudals (not sexed), has 7-7 supralabials and the dark four-striped body pattern (paravertebral pair, and each lateral stripe on adjacent parts of third and fourth scale rows) of *C. v. vittatus* (rather than *C. v. viduus*, Smith 1941).

A loose piece of paper in the specimen jar bears the handwritten locality of Hacienda de Gabriel, Durango, Mexico, C. Lopez, and the date 6-1919 (and also the AMNH number of 14217). These same collection data are also transcribed on the jar label (plus "Det. Wellman") and in the AMNH Catalog. The AMNH Accession Record (Number 21766) notes the *Conophis* specimen as part (total of 3 amphibians, 12 reptiles) of an exchange from "Mexico & Lower California" received from Carlos Lopez, Museo de Historia Natural, Mexico City, Mexico, 27 August 1919. Otherwise there are no field notes, field tags, or correspondence.

The locality "Hacienda de Gabriel" cannot be found on any map in the general area plotted for this locality by Wellman, and no such locality in the general area is listed in a U.S. governmental gazetteer (1956). An uninvestigated possibility is that the placename has been changed (e.g., in Durango the old names Estación Coyotes and Sombreretillo [among others] have been changed, respectively, to Morelos and Doce de Diciembre). Baker and Greer (1962:55) listed "Mt San Gabriel" and "San Gabriel" as unknown localities in Durango; however the mammal species associated with these placenames (Baker and Greer 1962:116, 120, 127, 130) all live in grassland habitat in eastern Durango (Rollin H. Baker, in litt., 11 June 1999), which is unsuitable for *C. vittatus*. There also is a San Gabriel in northern Durango just west of Villa Ocampo (off Highway 45), but the area is not appropriately tropical for *Conophis*.

Wellman's impetus for plotting this locality in extreme south-

ern Durango remains unknown. *Conophis vittatus* is not unexpected in this tropical part of southern Durango, an area particularly remote and not easily accessible even today. The species is known from Jalisco, but I am not aware of any specific, published localities in Nayarit (as noted by Zweifel 1959), and the species is not recorded from Sinaloa (Hardy and McDiarmid 1969). Until voucher specimens or other evidence can be obtained, *C. vittatus* is deleted from the Durango herpetofauna.

Acknowledgments.—I thank Alan Resetar for courtesies rendered during an FMNH visit, Linda Ford (AMNH) for transmitting data of acquisition anent the *Conophis*, and Paulino Ponce-Campos (Guadalajara, Jalisco) for a prolonged but unsuccessful attempt to validate the occurrence of the alleged locality for *Conophis* in Durango.

Perhaps the most important innovation of the fourth, 1999 edition of the International Code of Zoological Nomenclature, in the context of maintenance of nomenclatural stability, is the adoption of a revised version of the *nomen oblitum* concept, bolstered by the new concept of *nomina protecta*.

The idea of providing exceptions to the Principle of Priority in order to maintain stability of nomenclature has been discussed in official, regulatory assemblages since the late 19th century. Agreement on the means to achieve that end was first introduced into zoological nomenclatural procedures in the first, 6 November 1961 edition of the Code, as the notorious *nomen oblitum* rule of Art. 23(b). That rule was retained in the 1964 second edition, but was rescinded effective 1 January 1973. The term appeared only in the glossary of the third, 1985 edition of the Code, although its objective was reinstated in a widely overlooked Art. 79. That Article allowed petition to the Commission for conservation of long-used names threatened by discovery of earlier synonyms unused for at least 50 years prior to the petition, during which time the junior name was consistently used by at least five different authors in ten different publications. Under those conditions the Commission was empowered to suppress the earlier name in favor of the later nomen conservandum.

During the 1961–1973 interval, nomina oblita were "not to be used unless the Commission so directs" (Art. 23(b)(ii).

The decision to reject Art. 23(b) of the first and second editions of the Code was based importantly on two objections. First, an ancillary provision of that Article (23(b)(i)) was that any unused senior synonym of a junior name in use for 50 years or more was to be submitted to the Commission for action—an intolerable burden on both the Commission and active researchers, involving delays of usually several years. The same objection pertained to the reinstated procedure of the third edition.

Second and equally important, the frequency of usage that was required, first specified in the third edition, did not meet the needs of workers dealing with names rarely cited in spite of their acceptance (e.g., for many invertebrates), as opposed to many vertebrates with far more usages of their names.

In reviving the *nomen oblitum* concept in the 1999 edition of the Code, the first objection to the older rule was countered in Art. 23.9.1, by permitting authors to take action themselves (Art. 23.9.1.1) in dealing with a senior synonym or homonym unused as a valid name after 1899 but that (Art. 23.9.1.2) antedates a junior synonym or homonym that has been used for the taxon concerned with a given frequency. That frequency is usage in at least 25 works, by at least 10 different authors, in the immediately preceding 50 years and encompassing a span of no less than 10 years. The prevailing usage is to be maintained when any author publishes the existence of those conditions.

The second objection to the former *nomen oblitum* rule, involving rarely cited taxa, is countered in the 1999 edition of the Code by the request that, where a question arises in such cases, the Commission should be petitioned to act, following the protocol of Art. 81.

The procedure for implementation of Art. 23.9.1 is outlined in Art. 23.9.2, which provides that

> "An author who discovers that the conditions of 23.9.1 are met should cite the two names together and state explicitly that the younger name is valid, and that the action is taken in accordance with this Article; at the same time the author must give evidence that the conditions of Article 23.9.1.2 are met, and also state that, to his or her knowledge, the condition of

Article 23.9.1.1 applies. From the date of publication of that act, the younger name has precedence over the older name. When cited, the younger but valid name may be qualified by the term *nomen protectum* and the invalid, but older, name by the term *nomen oblitum*. In the case of subjective synonymy, whenever the names are not regarded as synonyms the older name may be used as valid."

An exemplary application of the *nomen protectum* rule of the 1999 Code is suggested by the case of *Thamnophis melanogaster* (Peters, 1864), as thoroughly discussed by Rossman et al. (1996). This name has been universally accepted for over a century as the valid name for its species, whereas Rossman et al. (1996) pointed out that *Tropidonotus* (*Regina*) *mesomelanus* Jan, 1863, beyond any reasonable doubt, is a subjective senior synonym of Peters' name, even though "it has not been used in place of the junior synonym *melanogaster* since the late-19th century."

Ruthven (1908) and Boulenger (1893) were well aware in their monographic accounts that Jan's name applied to Peters' species, but both rejected it. They were not willing to accept Jan's very briefly characterized first proposal (1863) of the name, probably because they regarded it as insufficient—a *nomen nudum*. Smith (1942) and Smith et al. (1950) cited Jan's 1863 name, accepting it as nomenclaturally occupied and not a *nomen nudum* but, as a last resort to maintain nomenclatural stability, the name was categorized in the latter work as a *nomen dubium*, of uncertain allocation, thus clearing the way for the long-accepted *T. melanogaster*. As long as it was so regarded, the latter name would be regarded as valid. No other device at that time would have achieved the same end, under the Code.

Rossman in Rossman et al.(1996:210) rejected the *nomen dubium* subterfuge, inasmuch as the number of scale rows (19), supralabials (8), preoculars (2), and postoculars (2) were given specifically for that species, and the ventral pattern was indicated (a midventral black line).

Therefore, as Rossman et al. (1996) pointed out, both names clearly belong to the same species; Jan's name should not be regarded as a *nomen dubium*. He still did not adopt Peters' name, however, being unwilling to upset a long-established nomenclature or to initiate the long-term process of petitioning the Commission for the conservation of Jan's name.

Fortunately, the 1999 Code provides the means to retain stability with *T. melanogaster* without twisting the meaning of *nomina dubia* to eliminate a change of its name at this late date to *T. mesomelanus*.

Accordingly, under Art. 23.9 of the 1999 Code, we here designate the valid name *Tropidonotus melanogaster* Peters, 1864, a *nomen protectum*, thereby taking precedence over *Tropidonotus* (*Regina*) *mesomelanus* Jan, 1863, a *nomen oblitum* in that context. As stated by Rossman et al. (1996:211), Jan's name has not been used as valid since the late 19th century. An impressive frequency of usage is indicated by 43 different articles with the name *Thamnophis melanogaster* cited in Smith and Smith (1976), and in 77 additional articles cited in Smith and Smith (1991). In the latter work 58 different authors are noted to have used the name within the period covered (mostly 1975–1991). As indicated in Uribe-Peña et al. (1999), usage of *T. melanogaster* persists to the present time. As a *nomen protectum* the name could now be changed officially only by action of the Commission.

Designation of *T. (R.) mesomelanus* Jan (1863) as a *nomen oblitum* removes it from consideration in the context not only of *T. melanogaster* Peters (1864) but also of any of its subspecies.

A variety of seemingly innocuous synthetic materials have become commercially available in recent decades, and many of these materials have proven to be harmful to animals when used or discarded in wildlife habitats, particularly marine environments (e.g., Gregory 1991, 1999; Laist 1997; Lucas 1992). Monofilament fishing line and beverage six-pack holders have been observed to entangle and kill birds and mammals (Serena 2000; pers. obs.). Plastic bags and nylon fishing gear are ingested by sea turtles and can result in esophageal and gastrointestinal blockage and death (Fritts 1982; Laist 1997; Lucas 1992; Starbird and Audel 2000). Lightweight, inexpensive monofilament netting constructed of polypropylene or polyethylene plastic has become widely available in recent years for a variety of terrestrial and aquatic uses. A common application for netting is the exclusion of birds and other wildlife from farm fields, gardens, orchards, vineyards, aquaculture ponds, and water bodies containing toxic substances (e.g., Bradford et al. 1991; Curtis et al. 1994; Fuller-Perrine and Tobin 1993; Henny et al. 1994; Lane and Higuchi 1998; pers. obs.). This material, often marketed as "bird netting," comes in a variety of square or rectangular mesh sizes (13–37 mm); most of the netting we have examined is constructed of sturdy, monofilament strands (ca. 0.25 mm thick) that are resistant to degradation from ultraviolet light. Although plastic netting has been reported as an entanglement hazard to birds (Bradford et al. 1991; Fuller-Perrine and Tobin 1993; Twedt 1980), we know of no similar published reports involving reptiles. In this article we report several observations of plastic netting causing entanglement and injury or death of snakes in New Mexico, USA.

During the summer of 1998, while providing a snake relocation service for residents of Placitas, Sandoval Co., one of us (MLW) observed four adult coachwhips (*Masticophis flagellum*) entangled in bird netting. Three of the snakes were encountered and released alive, and the fourth had apparently died from overheating after being trapped in full sunlight. Two of the live snakes (unsexed) were found in the same netting (Fig. 1) and were apparently trapped at the same time, possibly during courtship. All four snakes were heavily entangled, apparently due to the twisting escape behavior characteristic of the species (Degenhardt et al. 1996; pers. obs.), and had suffered lacerations from the tightly-wrapped netting strands. In each case the netting had been placed in yards to protect fruit trees from birds or flower gardens from cats.

Plastic netting is also incorporated in some types of erosion control blankets, used to stabilize and revegetate barren slopes in construction and reclamation projects. Woven mats of seed-implanted jute or straw are layered between two sheets of netting and anchored to a slope (Munshower 1994). The organic ingredients of the blankets decompose within 1–3 years, but the plastic netting may persist in the environment for 4 years or longer (pers. obs.) and pose an entanglement hazard to wildlife. On 27 May 1998, one of us (TLB) encountered a dead adult male *M. flagellum* (162 cm TL) entangled in discarded plastic netting at a dump site near Abiquiu, Rio Arriba Co. (Fig. 2). The netting strands were tightly wrapped around the anterior part of the snake's body and had cut through the ventral and lateral scales. The netting appeared to have been part of a straw erosion control blanket. On two different occasions in summer 1997, one of us (CE) found two adult bullsnakes (*Pituophis catenifer*) that had become entangled in netting (37 x 20 mm mesh) from an erosion control blanket at a reclaimed ore-mill site near Pecos, San Miguel Co. Both snakes were cut loose and released; one appeared unharmed but the other had suffered lacerations from the netting strands and possibly an injured spine during its entrapment. The surrounding hillside was covered with anchored sheets of netting through which grasses had sprouted. We do not know how extensively erosion control blankets with plastic netting are used, although we have observed similar "netted" hillsides associated with roadside revegetation projects throughout northern New Mexico. Use of plastic netting for this

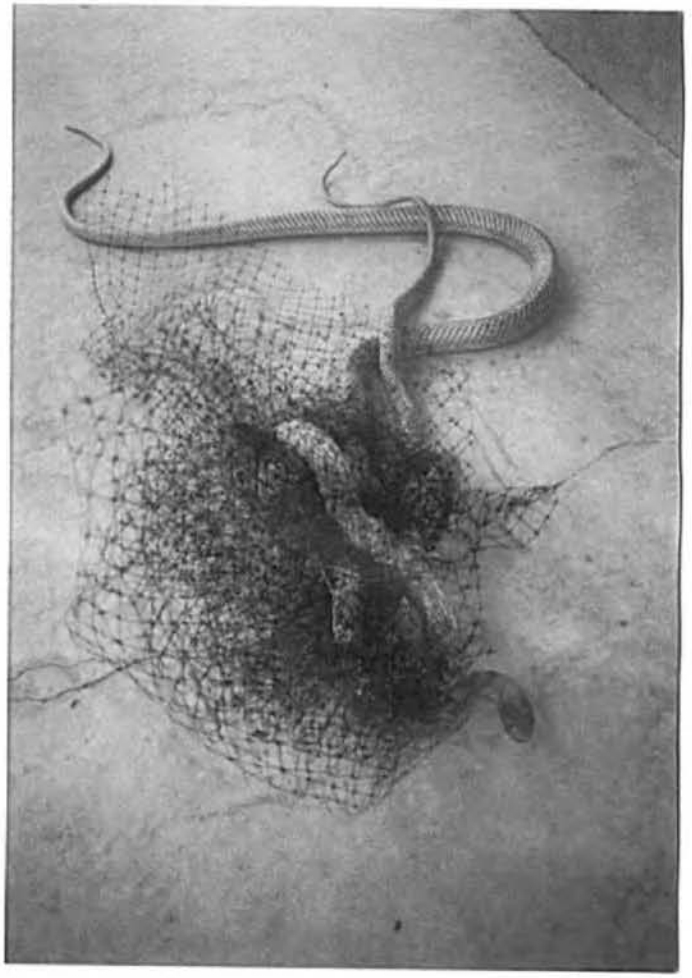

FIG. 1. Two live adult *Masticophis flagellum* entangled in plastic netting used to exclude birds from a fruit tree in Sandoval Co., New Mexico.

application is not necessary, however, as many netting-free varieties of these products are presently marketed. In recognition of netting's potential adverse effect on some species, a manufacturer of erosion control blankets in the United Kingdom recently advertised that its product is made purely of natural fibers and "does not rely on ecologically undesirable plastic netting (which presents a snagging risk to wildlife)" (Hy-Tex [UK] Limited, in litt.).

We believe that plastic netting with greater mesh sizes (e.g., ≥ 37 x 20 mm mesh, such as observed at the Pecos site) may be most hazardous to snakes because it allows large, heavy-bodied individuals with rough scales to become snagged and entangled when crawling between the strands. Large climbing species, such as whipsnakes (*Masticophis* spp.), may also encounter netting more often when it is used to exclude birds from trees and shrubs. Small snakes may not have a similar risk of entanglement in netting, even when the mesh size is small, due to their lighter body weight and smoother scales. Large snakes also may be more prone to entanglement in other man-made net-like materials. Campbell (1950) reported the entanglement of two "average sized" western diamondback rattlesnakes (*Crotalus atrox*) which became wedged in 1-inch (25-mm) mesh poultry ("chicken wire") fencing used in an outdoor quail pen in New Mexico. Similarly, a *C. atrox* and a *P. catenifer* were found entangled in poultry fencing in Arizona (E. Nowak, pers. comm.). Poultry fencing has been extensively used for many purposes for decades, and is still more widely available than plastic netting. However, we believe netting poses a greater entanglement hazard in most situations because of its durable, thin strands, its flexibility, and its placement on the ground or over vegetation where snakes are likely to encounter it.

Our observation that plastic netting is a hazard to reptiles is not unique. In 1999, we inquired via electronic mail if other herpetologists had observed reptiles entangled in bird netting or similar materials. Our inquiry yielded several responses describing snake entanglement, including observations of racers (*Coluber constrictor*) and ratsnakes (*Elaphe obsoleta*) injured or killed in vertically-hung netting in Maryland (F. Gould, pers. comm.); kingsnakes (*Lampropeltis getula*), *E. obsoleta*, and *M. flagellum* entangled and sometimes killed in netting used to exclude snakes from bluebird nest boxes in Texas (N. Ford, pers. comm.); and a *C. atrox* entangled and severely injured in netting at an Arizona home (E. Nowak, pers. comm.). In addition to snakes, specimens of desert spiny lizards (*Sceloporus magister*) were found entangled and killed in netting used to exclude birds from a brick-lined spring in Nevada (A. Heindl, pers. comm.). One respondent noted that this material has been effectively and safely used to capture snakes in Australia, provided that the netting snare is visited frequently (P. Mirtschin, pers. comm.). Plastic netting has also been used in water as a snare for semi-aquatic snakes (Lutterschmidt and Schaefer 1996).

FIG. 2. A dead adult *Masticophis flagellum* entangled in plastic netting from an erosion control blanket in Rio Arriba Co., New Mexico.

The widespread use of plastic netting and the number of documented incidents of snake entanglement, injury, and death warrants examination of its impact on reptile populations and other wildlife. An alarming characteristic of this material is its resistance to degradation, which allows it to persist for years in the environment as an entanglement hazard, even when discarded. Fuller-Perrine and Tobin (1993) noted that stiff plastic netting poses less of an entanglement hazard to birds than the more flexible varieties on the market; it is likely, therefore, that some forms of netting may be relatively "wildlife safe." We encourage other individuals who encounter animals entangled in plastic netting to document the circumstances (i.e., the species, size, and condition of the victim; and the variety, application, and mesh size of the netting) and to inform the manufacturers and users of netting of its potential hazard to wildlife.

Acknowledgments.—We thank Neil Ford, Frank Gould, Alex Heindl, Peter Mirtschin, and Erika Nowak for reporting their observations. Jennifer Lovato provided technical assistance with the manuscript.

A Breeding Population of American Crocodiles, *Crocodylus acutus*, on Roatán, Islas de la Bahía, Honduras

HINRICH KAISER
ELMER J. R. SIHOTANG

Crocodylus acutus is widely distributed along both the Pacific and Caribbean coastlines of Central America, it has a circum-Caribbean island distribution, and its range extends east along the Caribbean coast of South America to the Orinoco Delta, and south along the Pacific Coast of South America into northern Peru, including some rivers in Colombia (Ernst et al. 1999). It inhabits primarily brackish water habitats, many of which have become heavily impacted by human efforts directed at insect control and coastal development. As a result, *C. acutus* have become extirpated from many historical localities and the species is currently considered vulnerable and monitored by CITES. In general, survey data for *C. acutus* are of poor quality, anecdotal, and patchy (Ernst et al. 1999).

Ernst et al. (1999) indicate the presence of *C. acutus* on the Bay Islands of Utila and Roatán off the northwestern coast of Honduras, but not on the easternmost island, Guanaja. The distributional information for the Islas de la Bahía in Ernst et al. (1999) was extracted exclusively from the seminal paper by Wilson and Hahn (1973) on the Bay Island herpetofauna (C. H. Ernst, pers. comm.), whose records were based on only three specimens, two from Utila (without further locality data) deposited in the United States National Museum of Natural History, and one from "near Roatán" in the Field Museum of Natural History. Other species lists of the Honduran herpetofauna (Meyer and Wilson 1973, Wilson 1983, Wilson and McCranie 1994) and the recent paper by Köhler (1998) provide no further information on the status of *C. acutus* on Roatán or the other Bay Islands. Based on the limited available information and on local anecdotes, Wilson and Hahn (1973) considered crocodiles to most likely have been extirpated on Utila and Guanaja, with the caveat that remote parts of Utila and Roatán might harbor small populations. Scientists conducting marine research in the Bay Islands through the Roatán Institute for Marine Sciences considered observations of crocodiles near Roatán and on Utila to be examples of strays from the well-known populations in the area of the Honduran coastal city of La Ceiba (Jennifer Keck, pers. comm.).

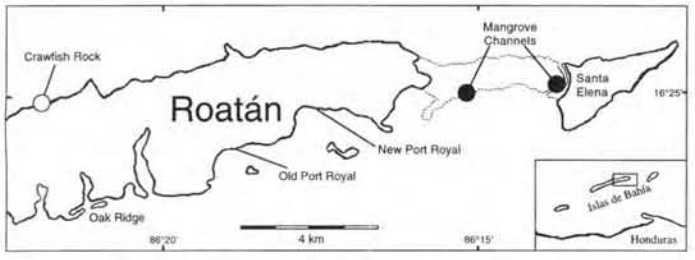

FIG. 1. Map of the eastern end of Isla Roatán, indicating crocodile sightings during 1999 (open circle) and 2000 (closed circles). Crawfish Rock is approximately identified by the open circle.

As part of our annual La Sierra University tropical biology field course we investigated the presence of crocodiles on Roatán, a plan fueled by the display of a small, dried crocodile (estimated SVL 60 cm, no collection data) in one of our accommodations. Our surveys were conducted in two attempts, the first (July 1999) involving a land-based search using information from local fishermen, the second (July 2000) taking into account habitat needs and behavior patterns of the species as well as the suggestion of Wilson and Hahn (1973) to search the undisturbed mangrove swamp at Roatán's eastern end.

Anecdotal information regarding crocodile sightings was easily obtained during our questioning of locals in July 1999, although exact locality data were usually unavailable. A fisherman from Crawfish Rock on the north coast of Roatán (Fig. 1) told of a specimen of approximately 1 m in length in a small brackish embayment ca. 500 m east of the village square that had been captured in 1998 by digging it out of its burrow. He informed us that another, larger crocodile was still in residence at that locality. The entrance to the burrow was on the south-facing side of a shallow estuary and was clearly identifiable by tail-drag markings in the sandy substrate. Looking into the burrow with flashlights revealed a large (estimated total length 200 cm) *C. acutus*. Our attempt to dislodge the animal from its burrow by digging or by capture with nets failed, though we experienced two unexpected encounters with a large snout and teeth in the process. Since we were unable to document the presence of crocodiles via specimen capture and photography, we resolved to take a different approach during the summer of 2000. Upon our return in July 2000 we were informed that the same crocodile we disturbed the previous year was still inhabiting the same burrow.

During our second attempt, we worked from a boat in the mangrove area at the extreme eastern end of Roatán (Fig. 1). Based on general activity patterns for crocodilians reported in the literature (e.g., Grenard 1991) and observations made by local fishermen, we opted to conduct an evening survey of the southern mangrove shoreline east of Old Port Royal and the north–south mangrove channel (Fig. 1) using flashlights and a halogen-enhanced search

FIG. 2. (Upper) The authors hold an adult female *Crocodylus acutus* (total length 206 cm) from the extensive mangrove swamps at the eastern end of Isla Roatán, Honduras. (Lower) Hatchling *C. acutus* from the same locality as the adult female. The hatchling had clearly visible umbilical scars and was found sitting on a mangrove branch with siblings visible within 1–5 m distances.

light. We encountered three individuals in the mangrove channel between approximately 1930 and 2100 h, of which one was observed in its entirety as it rested submerged in a narrow, shallow side channel, from which it subsequently escaped beneath the boat. In a larger side channel near New Port Royal we discovered at least seven hatchlings and an attendant adult female (total length 206 cm; Fig. 2), which was captured and released.

Based on these observations, we can conclude that Isla Roatán is inhabited by a viable, reproductively active population of *Crocodylus acutus* and does not merely harbor occasional mainland strays. Furthermore, our preliminary observations lead us to believe that any mangrove habitat on Roatán is potential habitat for these animals, and that future surveys will show a continuous coastal distribution for crocodiles in Roatán waters.

Anecdotal information regarding the presence of crocodiles on Guanaja indicate that on that island, just as on Roatán, a healthy breeding population existed prior to 1998. This is contrary to the information provided by Wilson and Hahn (1973), who reported that crocodiles had not been seen "for many years." At the time of their report, however, the human population of Guanaja was much less mobile and therefore less able to make observations on an island with a then poorly developed infrastructure. The island was heavily impacted by Hurricane Mitch in October 1998. During this devastating storm almost all mangrove habitats on Guanaja were destroyed, and only remnant mangrove patches in the northeast of the island may now be available as crocodile habitat. While we have no firm data to verify the presence of *C. acutus* on Guanaja at the time of this writing, we fully expect to obtain confirmation during future installments of our field course.

Acknowledgments.—We thank Allan Hyde, Shawn Hyde, and Bucky Weeks for facilitating our trips to Roatán. The able assistance of Jennifer Keck of the Roatán Institute for Marine Sciences and Julio Galindo of Anthony's Key Resort in arranging research space and inter-island transportation is gratefully acknowledged. Financial arrangements of our visits to Roatán are made possible through the careful planning of Esther Kinzer and Jorge Heyde. This is Tropical Field Biology Contribution No. 2 from the Department of Biology at La Sierra University.

Bone growth is known to be a cyclical phenomenon in many amphibians and reptiles, particularly in those that inhabit geographical areas experiencing marked annual temperature fluctuations (Castanet and Smirina 1990; Esteban et al. 1996; Hemelaar 1981; Smirina 1994; Wake and Castanet 1995). Furthermore, this cyclicity in osteogenesis results in formation of growth marks in bones which are used as indices for the process of aging (Smirina 1994). The validity and the reliability of the use of bone growth marks in estimating the age and longevity of amphibians have been reviewed thoroughly (Castanet and Smirina 1990; Esteban et al. 1996; Smirina 1994). Experimental studies have confirmed that the formation of these growth marks is annual in temperate amphibians (Hemelaar 1981; Hemelaar and van Gelder 1980; Tejedo et al. 1997). By enumerating bone growth marks in either the phalanges or long bones of limbs, age has been estimated for a number of temperate zone amphibians (references in Castanet and Smirina 1990; Castanet et al. 1996; Esteban et al. 1996; Smirina 1994). Whether similar growth marks also occur in the bones of amphibian species inhabiting areas with less marked annual tem-

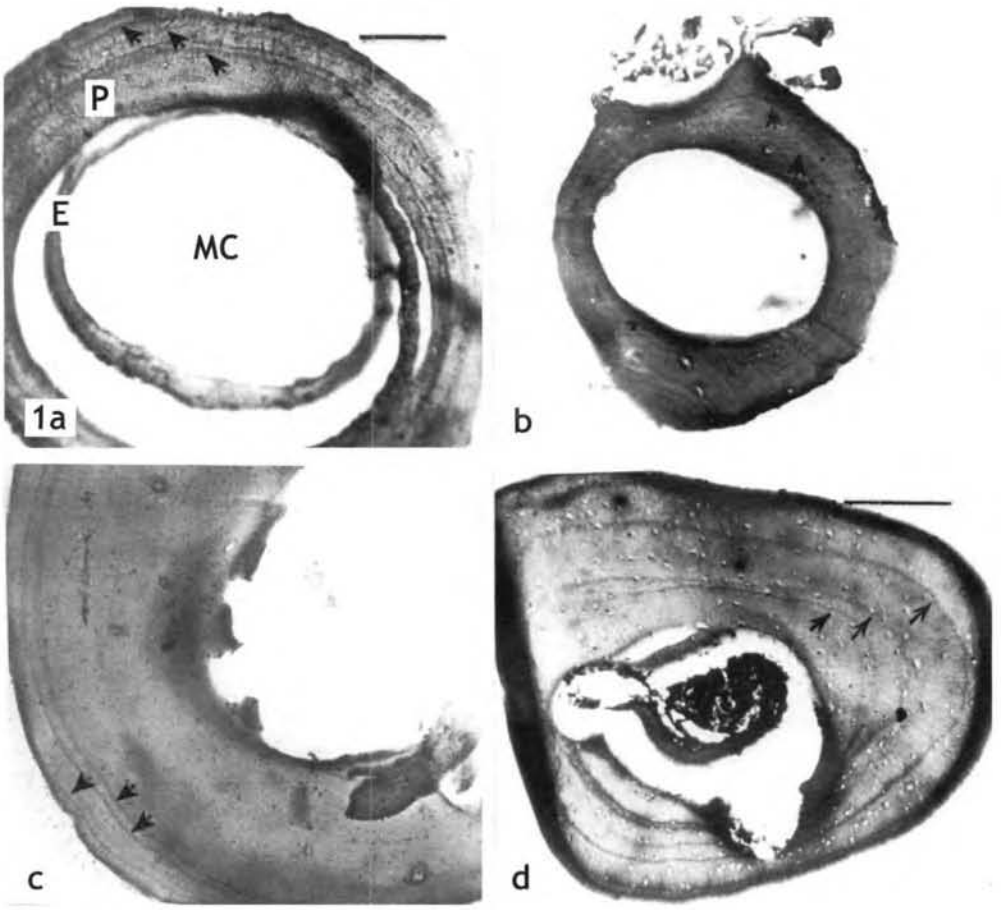

FIG. 1. Cross sections of (A) phalanx of *P. maculatus*,(B) phalanx of *B. melanostictus*, (C) phalanx of *R. tigrina* (scale line = 200 µm) and (D) femur of *M. ornata*. Scale lines = 100 µm. Arrows indicate lines of arrested growth (LAGs). (Abbreviations: MC = marrow cavity; E = endosteal layer; P = periosteal layer).

The hematoxylin stained cross sections of the phalanges/femurs showed a central bone marrow cavity surrounded by an inner narrow endosteal layer and outer relatively broader periosteal bone layer (Fig. 1). In the periosteal layer we observed a series of thin darkly-stained chromophilic lines separated by wider light purple rings with sparsely distributed osteocytes; the former were interpreted as lines of arrested growth (LAGs) and the latter as growth rings (Figs. 1A–D). In the phalanges of *P. maculatus*, 1–3 LAGs were observed located at the periphery close to each other (Fig. 1A); body size and number of LAGs showed a high degree of correlation (r = 0.86). But, in *B. melanostictus* (Fig. 1B), LAGs (1–4) were faintly stained and distributed equidistantly; there was a good correlation (r = 0.75) between body size and LAGs. One to five LAGs were observed in the phalanges of *R. tigrina*, their distribution was as in *P. maculatus* (Fig 1C); the number of LAGs correlated with the body size (r = 0.84). In the femurs of *M. ornata*, 1–4 LAGs were observed that were darkly stained, distinct and located equidistantly (Fig. 1D); body size and number of LAGs were correlated (r = 0.74).

perature fluctuations, such as the tropics, is not known (Esteban et al. 1996). In the present study we attempted to detect the presence of growth marks using skeletochronology in four species of anurans inhabiting Dharwad (15°17'N, 75°3'E) from southern India where annual variation in mean temperature does not normally exceed 10°C.

Specimens of *Rana tigrina* (SVL = 9–17 cm; N = 40), *Polypedates maculatus* (SVL = 3–6 cm; N = 8), *Bufo melanostictus* (SVL = 5–11 cm; N = 50), and *Microhyla ornata* (SVL = 1.5–2.5 cm; N = 40) were collected from areas surrounding Dharwad between June and December 1997. Following capture, the animals were taken to the laboratory where body weight (g) and body size (cm) were recorded. The fourth (longest) toe was removed from both the hind limbs under mild ether anesthesia and fixed in 10% formalin; however, specimens of *M. ornata* were too small so femurs were used for skeletochronology instead of phalanges. Digits/femurs were washed in water for 1–2 h and demineralized in 5% nitric acid. They were washed overnight in water to remove traces of formalin and nitric acid, and then preserved in 70% alcohol before processing for paraffin embedding. The sections (8 µm thick) of distal phalanx/femur were cut on an ordinary microtome and stained with Harris hematoxylin (Pancharatna et al. 2000). The sections were observed under a compound microscope for the presence of growth rings, which were enumerated when present.

Although it is known that the formation of bone growth marks in temperate anurans is a result of annual temperature fluctuations, the presence of similar growth marks is also reported in the limb bones of *Rana perezi* inhabiting the warm temperate climate of the Mediterranean region, which does not experience marked winter or summer inactive periods (Esteban et al. 1996). The recent study of Pancharatna et al. (2000) also reveals the presence of LAGs in the phalanges and limb bones of the Indian skipper frog, *Rana cyanophlyctis*. The results of the present study demonstrate that growth marks comparable to those found in temperate amphibians are detectable in the cross sections of limb bones/phalanges of four species of tropical anurans. The fact that all these anurans exhibit seasonal variation in body mass, fat body mass, gametogenic and breeding activity (Kanamadi and Hiremath 1993; Kanamadi and Jirankali 1991; Kanamadi et al. 1989; Pramoda and Saidapur 1984) suggests that bone growth may be a cyclical phenomenon leading to the formation of LAGs. Further, the positive correlation between body mass and LAGs of these anurans indicates that larger individuals have experienced a greater number of growth cycles and therefore may be older. Further study is required to determine whether growth cycles are strictly annual, and if growth marks can be treated as year rings.

Brett Stearns Award for Chelonian Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round-trip transportation and limited per diem expenses—to researchers who wish to visit our collections to support their work in chelonian biology. Preference will be given to graduate students.

Proposals should include a short, one page description of the research project and a budget. In the case of graduate students, a letter of support from the student's faculty advisor is required.

Proposals are due on 15 October 2001; notification will be made by 1 December 2001. Awardees are expected to complete their Academy visit by 15 September 2002. Please call (415) 750-7039 for further information.

Proposals should be sent to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

The CAS chelonian holdings are included in the Department of Herpetology database:

and

VICENTE YNGENTE
Warden, Polillo Town, Quezon Province, Philippines

Although many ingenious methods for catching arboreal lizards have been described (e.g., Durtsche 1996; Zani and Vitt 1995) none has proved suitable for large cryptic species such as *Varanus olivaceus*, a partly frugivorous monitor lizard from the Philippines. The animals are not attracted to carrion, leading Auffenberg (1988) to suggest that they could only be caught with the use of dogs. However, his results suggest a mortality rate of over 50% using this method which is unacceptable for a fully protected and threatened species. To facilitate future studies of the lizard, methods of capture that could be used repeatedly without significant risk to the animals were assessed around Sibulan Watershed Reserve on Polillo Island, Quezon Province, during July and August 1999. One successful method is the trap described below, which warrants further attention as a potentially useful tool for non-destructive studies of *V. olivaceus* and other shy arboreal lizards.

The "Mangmaty trap" is based on a traditional trigger-sprung trap used widely in the Philippines. Materials required are rope or vines, a 150-cm length of parachute cord with a running noose tied at one end ("noose string"), a "loop" 30 cm x 16 cm (or of a diameter sufficient to admit the target animal) made of flexible branches or vines and two 5-cm diameter wooden sticks; 30 cm ("trigger stick") and 4 cm ("short stick") long. A target tree is selected and rope or vines tied round the trunk to which a wall of vegetation is attached, blocking off all but a 30 cm passage on the side of the upward slope (Fig.

FIG. 1. Target tree with barrier attached.

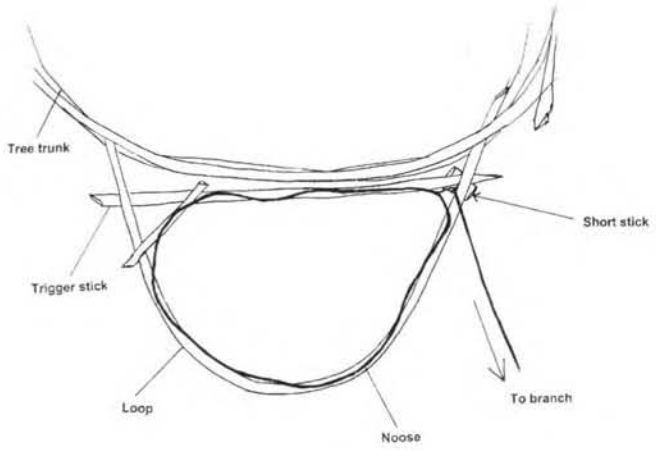

FIG. 2. Trigger mechanism for tree trap.

1). The loop is put over this route, attached to the trunk by wedging it into the ropes or vines that are wrapped around the tree. The noose and trigger mechanism is attached as shown in Fig. 2. The noose string is tied to the 4 cm stick at the base of the fully extended noose and the end tied to a firmly anchored tensioned branch. The short stick is wedged under the loop with the trigger

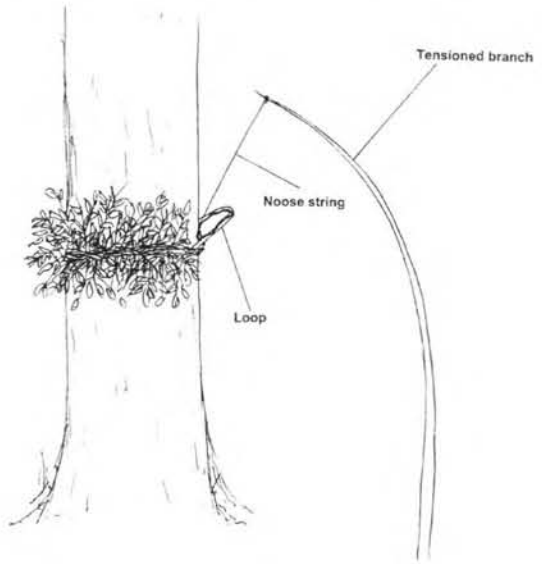

FIG. 3. Tree trap showing angle of loop.

stick. Any corner which the lizard could slip through is blocked with another small stick that rests on the trigger and support. An animal passing through the loop and putting pressure on the trigger stick will cause the small rod to come free, tightening the noose. Setting the loop at an angle on the trunk (Fig. 3) greatly increases the sensitivity of the trap and ensures that the noose closes around the torso rather than the neck. The tensioned branch to which the noose string is tied is bent only enough to ensure the noose is pulled tight, not to pull the animal off the tree. The illustrations show a trap designed to catch animals descending the trunk. By setting the trap upside down, ascending animals can be targeted, or two traps set per tree. Spool and line tracking of *V. olivaceus* indicated that they usually climb and descend trees on the side facing the higher slope of the ground (Fig. 1). Setting traps on this side of the trunk may therefore increase the likelihood of capture.

Acknowledgments.—Thanks to Matias, Pido, and Ricky Bulalacao, and Augusto Zafe for help with field work. Thanks to DENR, Polillo, Mrs. Doris Almeda, L. Afuang, A. T. Dans, J. C. Gonzales, and W. Oliver for logistical support. This work was part of the Oxford University/University of the Philippines at Los Banos Polillo Expedition 1999, partly financed by a BP Conservation Award.

Refinement of Neutral Red Staining for the Short-Term Marking of Tadpoles

Many ecological and behavioral studies depend on effective marking techniques to follow the response of individuals or unique cohorts of animals. Although techniques such as toe-clipping, tagging with waistbands, branding, or injection of dyes can be effective for larger-bodied amphibians, especially adults (Donnelly et al. 1992), the marking of small and delicate amphibian larvae has long been problematic. Attempts to solve this problem have led to a number of different techniques, including tail notching (Turner 1960), tail tags (Rice et al. 1998), injecting or spraying of dyes (Anholt et al. 1998; Seale and Boraas 1974; Taylor and Deegan 1982), and staining (Guttman and Creasey 1973; Herreid and Kinney 1966; Travis 1981). Although several of these techniques work well (e.g., Anholt et al. 1998), others may be too labor-intensive for marking large numbers of tadpoles (Rice et al. 1998) or have not been well-evaluated for detrimental effects (e.g., Guttman and Creasey 1973; Taylor and Deegan 1982; but see Travis 1981). In the process of conducting experiments on habitat selection and predator avoidance behavior of anuran tadpoles, we refined the basic technique of using neutral red stain as described by Guttman and Creasey (1973). Here we report the results of an experiment to determine whether the concentration of stain or the immersion time is most important in producing clearly marked tadpoles, and for distinguishing marked from unmarked tadpoles in laboratory aquaria. In addition, we wanted to find a concentration of stain that was effective in marking tadpoles but that did not

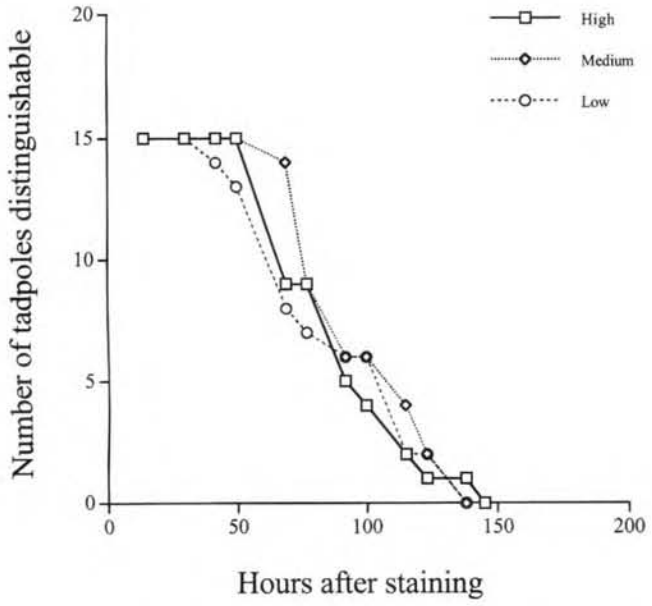

FIG. 1. The number of tadpoles stained at three concentrations that are distinguishable from unstained control tadpoles over time. Each data point represents the cumulative total from three containers of 5 tadpoles each.

compromise their survival (i.e., 8.7% mortality reported by Guttman and Creasey 1973) and minimized effects on growth (Travis 1981).

We manipulated the concentration of neutral red stain (source Chroma-Gesellschaft, Schmid GmbH & Co., Germany) using the lowest concentration (0.002%) reported by Guttman and Creasey (1973) plus two lower concentrations (0.0008%, 0.00125%; the latter was also used by Travis 1981). These solutions were prepared by mixing appropriate amounts of powdered stain in dechlorinated tap water just prior to use. At the same time, we manipulated the immersion time of tadpoles in the stain (1, 2, and 3 hours). Five tadpoles of *Rana temporaria* (Gosner stages 28–30, approx. 100 mg) were stained in each of the 9 treatment combinations. Within a few hours of staining, the five stained tadpoles were placed into white plastic dishpans containing 3 L of clean, aged tapwater along with five unstained tadpoles from the same cohort. Every 12 hours, we counted the number of stained tadpoles of each treatment which we could distinguish from the unstained tadpoles by the naked eye and without handling.

Stained tadpoles appeared reddish-brown in color over their whole body (tail fins appeared brighter red than the body) relative to control tadpoles under standard laboratory lighting. These tadpoles were sluggish immediately following immersion in the stain but resumed normal activity within 10 minutes. No mortality was observed in any test tadpoles. Staining was highly effective at all concentrations for approximately 50 hours, then gradually faded to background levels after 130–140 hours (Fig. 1). The three concentrations of neutral red exhibited similar patterns of fading (ANOVA; $P > 0.05$), indicating that the lowest concentration was just as effective as the highest concentration. However, immersion time did have an effect on stain persistence (Fig. 2). Longer immersion time resulted in tadpoles retaining color longer than tadpoles exposed to short immersion times (ANOVA; $P < 0.05$; Fig. 2). Although all immersion times resulted in tadpoles being highly distinguishable after 40–50 hours, the longest immersion time (3 hours) resulted in effective marking for 130–140 hours whereas the shortest immersion time (1 hour) resulted in complete fading after just 90 hours (Fig. 2). There was no interaction effect of concentration and immersion time (ANOVA; $P > 0.05$).

Our experiment indicated that increasing immersion time was the safest and most effective method for increasing stain persistence time. We avoided using the higher concentrations reported in the literature because our experience has indicated that some mortality can occur at the highest levels (Guttman and Creasey 1973; Travis 1981). Based on these findings, we began using the lowest concentration of neutral red (0.0008%; 8.0 mg per liter of water) in combination with a 2 or 3 hour immersion period for tadpoles in subsequent experiments. To control for any unknown confounding effects that the stain might have on tadpoles in these studies, we observed one stained species cohort and one unstained species cohort at a time and then alternated the stained species with each subsequent replicate observation. We have used these procedures repeatedly and successfully on four species, *Rana temporaria, R. lessonae, R. ridibunda*, and *R. esculenta* in short-term studies ranging from feeding behavior to predator avoidance (e.g., Rist et al. 1997). However, we recognize the potential for interspecific variation in stain retention or harmful effects, thereby suggesting that plans for extensive use of neutral red might include preliminary tests of effectiveness.

Since our experiment we have found that Waldman (1981, 1982, 1984) used neutral red effectively on *Rana sylvatica* and *Bufo americanus* tadpoles at even lower concentrations (0.00025% aqueous solution) with longer immersion times (12 hours) for 5–30 days post-staining. Waldman (1981, 1982, 1984) also used methylene blue (0.00025% aqueous solution with a 12 hour immersion time) and reported it to be effective on *R. sylvatica* and *B. americanus* tadpoles up to four weeks post-staining.

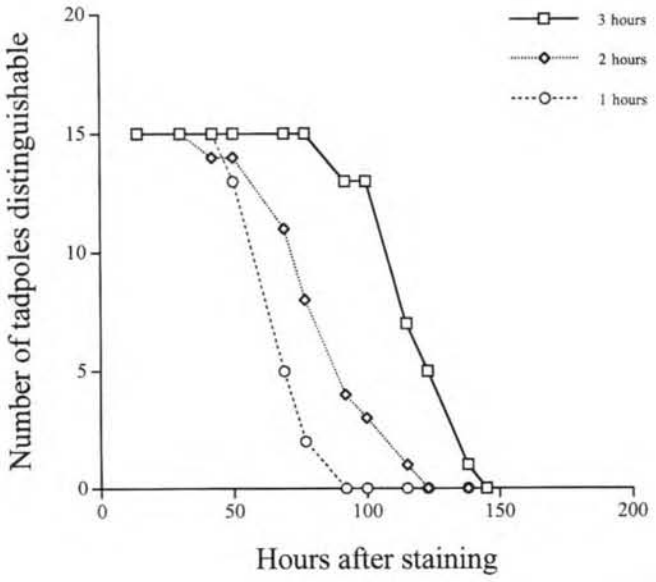

FIG. 2. The number of tadpoles stained at three immersion times that are distinguishable from unstained control tadpoles over time. Each data point represents the cumulative total from three containers of 5 tadpoles each.

Because of neutral red's limited utility in multi-group competition or predation studies, it would be desirable to find other equally suitable stains that would expand the range of colors available and the range of studies possible. Nevertheless, by itself, the neutral red staining technique described here is highly efficient and safe for short-term observations because of the ease of marking large numbers of individuals at one time.

**Present address: Department of Biology, Lehigh University Bethlehem, Pennsylvania 18015-3190, USA*

Accurately determining prey selection and foraging events is essential for a complete understanding of predator foraging ecology and their impact on prey communities. Obtaining such information from snakes can be exceedingly difficult due to their secretive nature. Generally, diet information is obtained through documented observations or stomach/scat analysis (e.g., McCartney 1989; Reinert et al. 1984; Uhler et al. 1939). Additional methods, such as forced regurgitation (e.g., Diller and Johnson 1988; Fitch 1987; Kephart and Arnold 1982) identify prey items, but this approach may disturb the snake's normal behavior. This paper presents the results of an effort to use Passive Integrated Transponders (PIT tags) as a means of positively determining foraging success and to obtain detailed information on prey selection by free-ranging timber rattlesnakes (*Crotalus horridus*).

PIT tags are small, glass encapsulated microchip transponders that can be easily inserted subdermally, and positively identify individuals through the use of an external PIT tag reader (Ball et al. 1991). PIT tags are energized by the external reader, require no battery, have unique tag numbers, and an indefinite life span. When implanted subcutaneously in ingested prey, PIT tags can be easily read through the body of a snake (MacGregor, unpubl. data). This allows for the determination of a successful foraging event and the precise identification of the ingested prey without handling or disturbing the snake.

As part of a long-term ecological study in the Pine Barrens of Ocean County, New Jersey (USA), 12 *C. horridus* (8 males, 4 females) were surgically implanted with AVM SM1 radio-transmitters (Reinert 1992; Reinert and Cundall 1982). Snakes were located with an AVM Instrument Company LA-12 receiver every 24–48 hours. While monitoring the rattlesnakes, Sherman live traps (58.9 cm x 22.8 cm x 19 cm) were used to capture small mammals. Trapping and tagging of prey occurred in 2 phases. Phase 1 involved trapping at known foraging areas, identified through previous radio-tracking efforts. Twelve grids with 36 traps each were operated for 7 consecutive nights between 15 May and 1 June 1998. All Phase 1 trapping was done prior to the snakes' arrival to the foraging areas. Phase 2 involved trapping with snakes during their active season. Phase 2 was a modified version of King and Duvall (1990), and consisted of 6 traps placed at 5 m intervals in a hexagonal pattern with the snake as the central point. Each time the snake moved, the traps were also moved, and reset in the same hexagonal pattern at the new snake location. Captured small mam-

mals were identified to species, aged, sexed, weighed and implanted with a 14 mm PIT tag (AVID MUSICC Chip™ Identification system #2023) following Ball et al. (1991). An external PIT tag reader (AVID PIT tag reader, model #052563 from AVID, Norco, California 91760-9972) was modified with an extension handle that allowed snakes to be scanned safely without disturbance. Snakes were scanned for the presence of PIT-tagged prey whenever a foraging event occurred or was suspected.

A total of 114 white-footed mice, *Peromyscus leucopus* were captured between May 1997 and August 1998; 82 were implanted with PIT tags. The average mass of all trapped mice was 20.6 g (S.E.= 0.46, N = 114). The PIT tag sample consisted of 56 males and 26 females of which 65 were adults and 17 were sub-adults. Six rattlesnakes consumed a combined total of seven PIT tagged mice. Although all rattlesnakes were observed feeding in at least one of the pre-trapped foraging grids, only one rattlesnake ate a tagged mouse while in the pre-trapped foraging grid. The majority of tagged mice were consumed while trapping with individual snakes. A young male rattlesnake ate a mouse that was PIT tagged during trapping efforts associated with a different snake. All seven mice consumed were male. The average mass of consumed mice was 23.4 g (SE = 1.70, N = 7). The tagged animals were eaten between 2 and 40 days after tagging. In addition, two mice perished during trapping efforts. These mice were implanted with PIT tags and subsequently offered, and eaten, by two snakes. The average rate of digestion (ingestion to defecation) was 15.4 days (SE = 0.80, N = 9). Eleven rattlesnakes consumed prey (as determined by visible food boli) while in one of the pre-trapped foraging grids; however, none of that prey had been PIT tagged. Analysis of scat from one of these snakes indicated that it had eaten a red-backed vole (*Clethrionomys gapperi*).

These results suggest that snake foraging studies can benefit from the use of PIT tags. PIT tags provided information on species, sex, and mass of consumed prey as well as the rate of complete digestion. In the present study, all consumed tagged mice were male despite the fact that trap efforts suggested that approximately one-third should have been females. Statistically, the average mass of consumed mice did not differ from the average mass of all available prey items (One-way ANOVA $F_{(05)\,(1,112)} = 2.3$, P = 0.13); however, consumed prey were among the heavier animals in the sampled population. Information on mass, age, and sex of prey items can be important in understanding selective pressures on prey. Certain individuals or types of prey may exhibit a behavioral or sociochemical susceptibility to predation (Gehlbach et al. 1971; Madison 1978; Reinert et al. 1984). For example, Madison (1978) found that black rat snakes (*Elaphe obsoleta*) and racers (*Coluber constrictor*) did not show sexual preference for meadow voles (*Microtus pennsylvanicus*); however, there was a non-random selection for lactating females and their litters, as well as heavy-bodied males. Female voles have a strong maternal nature and as a result, may remain with young when intruders are present (Madison 1978). This behavior, as well as the probable high activity levels and reproductive activity of large males, may account for their higher predation risk (Madison 1978). Diet studies of this nature are limiting; however, PIT tags could easily provide the necessary detailed information to understand the degree of prey selection.

The use of PIT tags, as described here, may be particularly informative for species that reliably revisit foraging sites during a single active season, or when the interest in foraging activities is restricted to a specific area (Fitch 1982; Kephart and Arnold 1982; Nelson and Gregory 2000). In most cases, vertebrate prey can be easily implanted with PIT tags, particularly when prey monitoring is part of the study (Diller and Johnson 1988; Galligan and Dunson 1979; King and Duvall 1990; Madison 1978; Reynolds and Scott 1982). In this study, the use of PIT tags was most successful while trapping with active individuals; however, such constant activity can be disruptive to normal snake behavior. Although foraging areas (Phase 1 trap sites) were accurately identified, adult rattlesnakes typically visited these sites only once each season (Reinert and Zappalorti 1988). Accordingly, the seasonal pattern of movement by *C. horridus* makes them a less than ideal candidate for PIT-tag foraging studies when prey monitoring is performed ahead of time.

Implanting PIT tags in prey prior to a snake's arrival to an area allows predators to forage naturally. Snakes can be scanned for ingested PIT-tagged prey with minimal or no disturbance and researchers can obtain reliable and detailed data on prey. The resultant information can increase our understanding of ophidian prey preference and its influence on prey, snake foraging ecology, and the interaction between predator and prey.

Acknowledgments.—This research was funded in part by a Theodore Roosevelt Memorial Fund grant from the American Museum of Natural History to GAM and by a grant from the New Jersey Trust for Public Lands Barnegat Bay Foundation to HKR and Robert T. Zappalorti. All research was conducted under a scientific collector's permit issued to HKR and R. T. Zappalorti by the New Jersey Department of Environmental Protection, Division of Fish, Game and Wildlife. We thank M. Maliga, L. Nolfo, A. Pai, and M. Wund for assistance in the field.

Identification of individuals within a population is necessary for most behavioral and ecological studies of wild animals. For long lived animals, such as turtles, the ability to recognize and follow individuals over time provides critical information on aspects such as growth, survivorship, residency, and migration. A variety of techniques and tags have been developed to mark individual sea turtles, ranging from subcutaneous passive transponders to autografts of differentially pigmented tissue (Balazs 1999). The greatest challenge in marking sea turtles is durability and readability of the tag over the lifespan of individuals, which can cover decades and involve a great amount of growth. Tag loss can affect estimates of population size, survivorship, and other demographic calculations (Frazer 1983).

Mrosovsky (1983) emphasized the importance of quantifying tag loss, and since then several studies have reported the retention rates of various types of tags and markers for different turtle species (Bjorndal et al. 1986; Frazier 1986; Limpus 1992; Parmenter 1993; van Dam and Diez 1999). In general, the rates of tag loss are particular to specific species and areas. For instance, for loggerhead (*Caretta caretta*) sea turtles in northern Australia, titanium flipper tags outperformed tags made from monel or plastic (Limpus 1992) while for hawksbill (*Eretmochleys imbricata*) sea turtles, plastic tags outperformed both monel and inconel tags (van Dam and Diez 1999). In the current study, we examined the rates of tag loss of two types of commonly used metal tags, monel and inconel, in hawksbill sea turtles found in near-shore habitats in the archipelago of Fernando de Noronha, in the southern Atlantic ocean.

Materials and Methods

The archipelago of Fernando de Noronha (3°50'S, 32°24'W), a Brazilian National Marine Park located approximately 380 km off the coast of Brazil, supports populations of juvenile hawksbill and green (*Chelonia mydas*) sea turtles in feeding areas close to shore. Since 1987, researchers of Projeto TAMAR-IBAMA, the national sea turtle conservation program in Brazil, have been monitoring these populations using a capture, mark, and recapture protocol (Sanches and Bellini 1999). Although turtles have been captured in eight different localities on the island, the majority of captures are made in Sueste Bay, which is easily accessible and contains a relatively large resident population of sea turtles. In all cases, individual animals were captured by hand during free dives with mask and snorkel, after which curved carapace length (CCL) and width, and mass were recorded and tags were placed on the front flippers.

We placed style 681 tags (National Band and Tag Company, Newport, Kentucky, USA) on the trailing edge of each front flipper, proximal of the first large scale immediately adjacent to the axilla (cf. Limpus 1992). Up until 1994, we used only tags made from monel, a nickel-copper alloy. After this, inconel tags (made from a nickel-iron-chromium alloy) were placed on all turtles en-

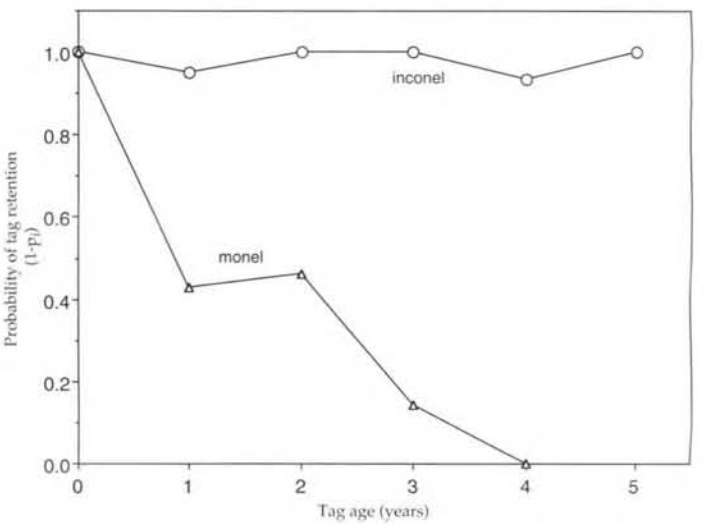

Fig. 1. Estimated probability ($1-p_i$) of tag retention over time for monel and inconel tags used on hawksbill sea turtles in Fernando de Noronha, Brazil.

countered for the first time, while for recaptured turtles, inconel tags replaced monel tags as the latter were found to be lost or unreadable. Recaptured turtles were checked for tags; encountered tags were checked for readability and also for their durability by pulling on the two sides of the tag at the same time. If unreadable, or if they opened when tested, they were considered to be "lost" and replaced with new tags. Probability of tag loss for the two types of tags was calculated using the following equation from Limpus (1992):

$$p_i = b_i/(a_i+b_i)$$

with **i** being the elapsed time in whole years since tag application;

$\mathbf{a}_i$ being the number of tags still present on turtles recaptured after **i** years since being attached; and

$\mathbf{b}_i$ being the number of tags lost on turtles recaptured after **i** years since being attached.

Standard error (SE_{pi}) was derived as: $\sqrt{[p_i(1-p)/(a_i+b)]}$, and the 95% confidence interval of p_i being $\pm$ [$(SE_{pi})(1.96)$]. Elapsed time since application was rounded up or down to the nearest year for recaptured tags. Only turtles recaptured at least once were included in the analysis.

Results

A total of 69 hawksbill turtles, ranging in size from 26.5 to 64 cm CCL at initial capture, have been recaptured one or more times in the near-shore waters of Fernando de Noronha since 1987. A total of 238 tags (145 monel and 93 inconel) have been deployed on these 69 turtles. The average durability of a monel tag was 334 days $\pm$ 24.9 SEM, which was significantly shorter than the average durability of an inconel tag, 851 days $\pm$ 56.5 SEM ($p<0.001$, Mann Whitney test, $U = 3325.5$).

Tag loss increased yearly for monel tags, reaching 1.00 after four years, while for inconel tags it remained low for up to five years (Table 1). The chance of an inconel tag remaining intact over time remained extremely high, whereas the longest duration a monel tag successfully remained on a turtle was three years (Fig. 1).

Both monel and inconel tags on recaptured turtles were susceptible to biofouling by green or red algae, and by calcareous algae, and usually had to be cleaned in order to be read. Monel tags typically displayed corrosion in the locking mechanism; oftentimes when we tested tags on recaptured turtles, the tag opened easily because the locking mechanism had deteriorated (Fig. 2).

Discussion

Because we tested the state of each tag every time a turtle was recaptured, in many cases we were able to record exactly where corrosion, if any, was occurring, and also to replace tags that were likely to have been lost if left in place. Corrosion of the monel tags, particularly in the locking mechanism, appeared to be an important contributor to the failure of these tags (Fig. 2). Monel tags displayed a poor rate of retention in hawksbill turtles feeding in the nearshore waters of Fernando de Noronha. This is consistent with other in-water studies which have also found monel tags to be inferior to tags made from other materials (Limpus 1992; van Dam and Diez 1999; but see Bjorndal et al. 1996 for contrary results for a nesting population).

The probability of tag loss for monel tags varied over time from initial tag application, with two-year-old tags having a slightly greater chance of remaining intact than one-year-old tags (Fig. 1). This suggests that there may be a variety of factors, in addition to corrosion, affecting tag loss in these turtles. For example, locations of the turtles varied, and differences in the seawater chemistry for particular areas may lead to deterioration at different rates. Also, subtle differences in the manufacturing of different batches of monel tags may affect rates of corrosion (Balazs 1999; Bjorndal et al. 1996). In contrast, the low level of tag loss for inconel tags in this study was relatively constant over time, and suggests that continued use of this tag during our study is warranted. Indeed, a nearly five-year-old inconel tag was mistaken for new on a hawksbill turtle tagged in Sueste Bay and recovered in Gabon, because the tag showed no signs of wear or corrosion (J. Fretey, pers. comm.).

Van Dam and Diez (1999) found that plastic tags had a greater retention rate than inconel and other types of tags in hawksbill captured on a feeding ground in the Caribbean. Although we have never used plastic tags, we have avoided them because it has been suggested that plastic tags increase the likelihood that turtles will become accidentally entangled in fishing nets (Nichols et al. 1998; Suggett and Houghton 1998). Although use of such nets is prohibited in the majority of waters around the archipelago of Fernando de Noronha, individuals in our study have migrated to other areas where they are likely to encounter nets (e.g., Bellini et al. 2000). It is interesting that van Dam and Diez (1999) reported that the loss of inconel tags in the Caribbean was restricted to turtles smaller than 35 cm CCL, whereas in our study, the majority of turtles captured were larger than 40 cm CCL (Sanches and Bellini 1999). Similarly, Prince (1996) found that both titanium and inconel tags were shed quickly by smaller juvenile sea turtles. Perhaps inconel tags would not perform well in Fernando de Noronha in smaller hawksbill individuals.

Passive integrated transponder tags, which are placed intramus-

cularly and then recognized with a special scanner, have been used with success in some projects (e.g., McDonald and Dutton 1996; Parmenter 1993; van Dam and Diez 1999). However, the relatively high cost of the tags and scanner and the impossibility of recognizing the tags without a scanner (e.g., by fishermen who accidentally capture sea turtles) have kept us from using them in our study.

Regardless of the efficacy of other tags reported by other sea turtle research projects, we have experienced high level of success with inconel tags (only 6 out of 97 tags have been lost over the past five years), and will continue to use them during our study. Indeed, we are currently replacing all monel tags with inconel on recaptured turtles, independent of the status of the tag, in order take advantage of the longevity of inconel tags. This is especially important for larger individuals, who are likely to migrate to other regions in the near future. Our results show that, as with almost all aspects of management of wild animals, evaluation and assessment should be done independently on a case by case basis. This is particularly important with respect for programs that rely on the tagging of sea turtles. It is highly recommended that each program evaluate the probability of tag loss, rather than extrapolating from other studies.

Acknowledgments.—We greatly appreciate the support and collaboration of various researchers and interns over the years in our ongoing capture, mark, and recapture study. Petrobras is the official sponsor of Projeto TAMAR-IBAMA. Additional support came from the National Marine Park of Fernando de Noronha - IBAMA, the Fundação Pró-TAMAR, and the Natural Sciences and Engineering Research Council (Canada).

The prairie provinces of Canada: Manitoba, Saskatchewan, and Alberta, were among the last regions of temperate North America to be adequately surveyed herpetologically. Not surprisingly, Manitoba, the easternmost of the provinces, was the first to have its amphibians and reptiles enumerated (Seton 1918). Detailed treatments of the herpetofauna of these provinces did not appear until much later still (Cook 1966—Saskatchewan; Preston 1982—Manitoba; Russell and Bauer 1993—Alberta). For Alberta, even regional herpetofaunal accounts or single species observations were unknown prior to the 20th Century. The first published records of amphibians and reptiles from Alberta are those of Preble (1908),

based on field observations made during 1903. Preble's account focussed on central and northern Alberta, especially herpetofaunally impoverished regions of the province. He recorded only a single reptile, *Thamnophis sirtalis parietalis*, which he stated was "common about Edmonton and along the road to Athabaska Landing." He also indicated that garter snakes (species unconfirmed) were reported to be present in the Peace River Valley, especially around Dunvegan, and "on the plains of Salt River," a tributary of the Slave River near the Alberta/Northwest Territories border. Harper (1931) also reported *T. sirtalis* to be common in the Edmonton area, based on observations made in May 1914.

The first European incursions into Alberta were carried out by the Hudson's Bay Company and the rival North West Company and were chiefly conducted with economic gains in mind. These commenced with the expedition of Anthony Henday in 1754 and continued with the subsequent journeys of Peter Pond (1778), David Thompson (several trips between 1786 and 1808), and Alexander Mackenzie (several trips between 1787 and 1793) (Hitchon 1967). The first expedition in which a naturalist participated was Captain John Franklin's Arctic Expedition of 1819–1822. The zoological results of this expedition were published by John Richardson (1829–1837) as *Fauna Boreali-Americana.* Not surprisingly, as the expedition chiefly investigated the most northerly areas of present day Alberta (incidental to its main focus on the coastal Arctic), this treatise contained no herpetological references. Some years later, however, Richardson (1851) became the first to publish an account of reptiles in the prairie provinces, noting the occurrence of garter snakes (as *Tropidinotus sirtalis*) on Serpent Lake in what is now central west Saskatchewan, not far from the modern Alberta border. Richardson, who had participated in Franklin's earlier voyages, recorded this observation as a member of the Arctic Searching Expedition, sent out to discover the fate of Franklin's ill-fated 1845 expedition in search of the Northwest Passage.

Through the courtesy of Dr. Bill Barr we have been alerted to what we believe to be the earliest reference to reptiles in Alberta. It derives from an unpublished journal by Æmilius Simpson (1826), a relative of Sir George Simpson (governor of the Hudson's Bay Company 1821–1856). Although Æmilius Simpson's place in Alberta history is minor, Port Simpson (now Lax Kw'alaams), on Dundas Island, British Columbia was named for him in 1834 (Galbraith 1957), and he is credited with introducing apples to what is now the state of Washington (Fallgatter 1998). Simpson was in the employ of the Hudson's Bay Company, which until 1870 controlled the present area of central and southern Alberta and much of western Canada. A single reference to reptiles occurs in the manuscript. It is based on observations made on Monday, 4 September 1826 when Simpson and his party were traveling west on the North Saskatchewan River, one of the chief rivers of central Alberta, and then a major trading route to York Factory on Hudson Bay (MacGregor 1972). At 7 AM that morning, Simpson reported passing the Stony River and at noon he took readings indicating his position as 53°45'34"N, 110°40'W. Simpson's journal account reads as follows:

> "Thick Fog in the Morning, followed by very Warm Weather during the Day. Thermometer at Noon 75°. We were favoured with a fair Wind for some hours, which gave our Crews considerable relief from the labour of Tracking. Along the North Banks I observed Boulders or Masses of limestone embeded in Clay. During the heat of the Day we passed great numbers of a small striped Black & green snake swimming from the South to the North Bank of the River & strewed along the Sandy Beach on the North Shore, as if enjoying the powerful influence of the Sun, & it appeared that those crossing were leaving the cold of the Northern aspect to gain the more pleasing heat of the southern exposure. The Evening having become cool we were less troubled by moskitos."

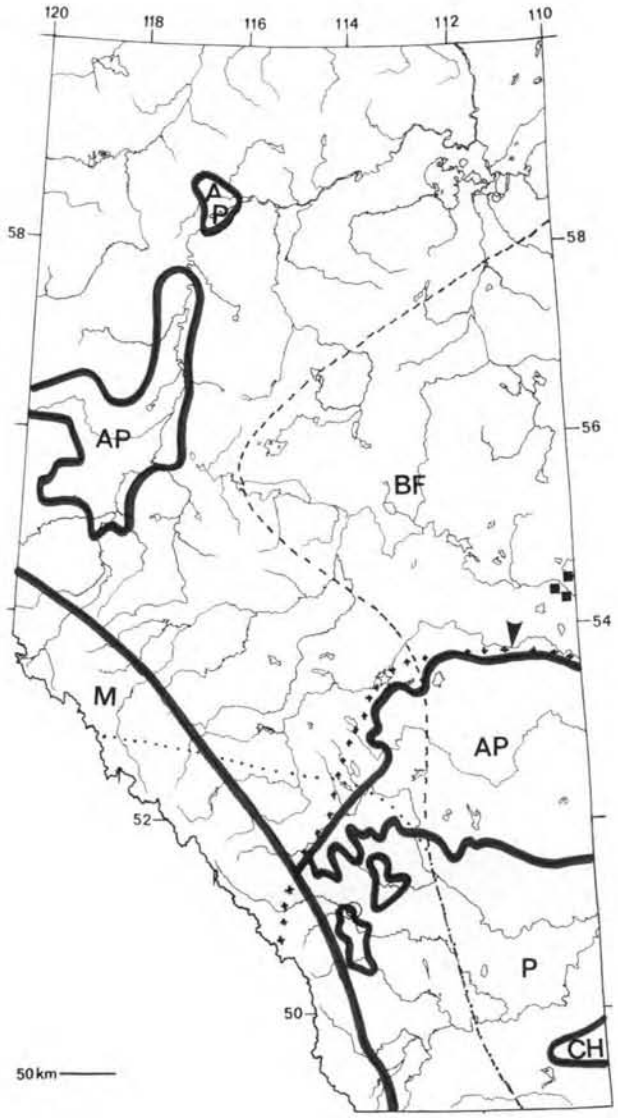

FIG. 1. Map of Alberta showing the location of Simpson's sighting of garter snakes (arrow) on the North Saskatchewan River on September 4, 1826. The present day margins of the continuous ranges of the three species of garter snake occurring in Alberta are depicted as follows: *Thamnophis sirtalis*—dashed line, distribution to the west of this line; *T. radix*— crosses, distribution to the south and east of this line; *T. elegans*— dots, distribution to the south and west of this line. The major biomes of Alberta are demarcated by heavy dark lines and are indicated as follows: AP — aspen parkland; BF — boreal forest; CH — Cypress Hills; M — Rocky Mountains; P — prairie. The only known records of *T. radix* from north of the North Saskatchewan River are indicated by solid black squares. The major Alberta population centers of Calgary and Edmonton are demarcated by a circle and a star, respectively.

Examination of Simpson's narrative and comparison with modern maps indicates that this reported position is slightly erroneous. On the previous day Simpson's party passed Dog Rump Creek, heading west. Dog Rump House, abandoned in 1829, was set up as the Moose Lake outpost of the Hudson's Bay Company in 1822. After abandonment the Hudson's Bay Company geographic names fell into disuse. This creek is now known as Atimosue Creek, and is located south of the town of Elk Point. On the morning of 4 September the party passed "the Stony River" (now known as Siler Creek) at 7 AM, and an island (now known as Fort Island) at noon. It is at this point that Simpson took his readings. The actual coordinates of Fort Island are 53°45'15"N, 111°10'W.

This information pinpoints a stretch of river that courses essentially due west and places the location of the snake observation between Fort Island and the point on the river crossed today by Highway 881 (53°45'15"N, 111°10'13"W). The bridge for this river crossing lies 10 km north of Myrnam, and this stretch of the river is 4.5 km due south of Lake Eliza. The location is situated approximately 117 km ENE of Edmonton.

Among Alberta snakes, the observation clearly must refer to a garter snake. Three species, *Thamnophis radix*, the plains garter snake, *T. elegans*, the wandering garter snake, and *T. sirtalis*, the red-striped garter snake are known from the province (Fig. 1). *Thamnophis elegans* is largely limited to the southwestern portions of the province, chiefly in the Rocky Mountain and prairie biomes. However, specimens are occasionally found much further north, and the species is often associated with rivers. All modern records from the vicinity of Fort Island are attributable to *T. radix*, and most are from localities in aspen parkland or prairie, although a few plains garter snakes have been collected in the boreal forest biome north of the North Saskatchewan River (Fig. 1). There is a large disjunction in eastern Alberta in the range of *T. sirtalis* between the immediate vicinity of Edmonton and the region of Lake Athabasca (north of 58°N) (Fig. 1), but this is likely to be artifactual and in part reflective of the conversion of the southeastern boreal forest biome to intensive agricultural use (Russell and Bauer 2000). Simpson's terse color description could fit either *T. sirtalis* or *T. radix*, and both species are adept swimmers, but the very similar accounts of Preble (1908) and Harper (1914) suggest that *T. sirtalis* may have been the species implied.

Although hardly detailed, and not supported by voucher specimens, Simpson's observations are significant in that they predate the earliest subsequent observations of Alberta reptiles by more than 75 years and constitute the first European record of reptiles in inland western Canada. It is likely that Simpson felt the sighting noteworthy because of the number of snakes involved. Several possibilities exist to explain the observation. The snakes he observed may have represented a late summer aggregation of gravid females comparable to that reported for *T. sirtalis* from the Interlake region of Manitoba (Gregory 1975). Alternatively, they may have been a mixed sex grouping exhibiting an autumn pre-denning aggregation. Finally, the observation may merely reflect high local natural densities in areas of high quality habitat, as have been reported for both *T. radix* and *T. sirtalis* (Rossman et al. 1996).

Acknowledgments.—We thank Bill Barr for bringing Simpson's observations to our attention and W. Leo Smith for providing access to the information in Richardson (1851). Pat Gregory provided useful comments on the manuscript.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 32, Number 1 (March, 2001).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). USA: TEXAS: Franklin Co: 8.2 mi N jct. Rt. 67/FM 1896, ca. 2 mi W on White Oak Creek Ranch. 29 April 2000. Toby J. Hibbitts and Terry L. Hibbitts. TCWC 84254–58. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA, and **TERRY L. HIBBITTS**, 602 Hilltop Circle, Wylie, Texas 75098, USA.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: ARKANSAS: Phillips Co: (N34°61.422, W90°61.646). SE 1/4 Sec. 7, T1S, R5E, jct. Phillips County Roads 211 and 239, St. Francis National Forest. 15 January 2001. L. K. Irwin and K. J. Irwin. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26050–070). Verified by Stan Trauth. A series of 21 "winterkill" individuals found in cypress-tupelo gum slough in bottomland hardwood forest at base of eastern versant of Crowley's Ridge. First record for county (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us) and **LISA K. IRWIN**, 103 Brooke Drive, Perryville, Arkansas 72126, USA.

EURYCEA TYNERENSIS (Oklahoma Salamander). **A CORRECTION**. A new county record for the Oklahoma salamander (*Eurycea tynerensis*) recently extended its geographic range 96.5 km S of Sequoyah County into the southcentral-most part of LeFlore County (Lutterschmidt et al. 1999, Herpetol. Rev. 30:230). Two salamanders were collected from an isolated pool along Cucumber Creek and were verified as *E. tynerensis* by R. D. Durtsche at the Oklahoma Museum of Natural History. Subsequently, the specimens have been re-identified as larval Many-ribbed Salamanders (*Eurycea multiplicata*) rather than *E. tynerensis*.

Distinguishing *Eueycea tynerensis* from larval *E. multiplicata* is extremely difficult and often requires experience in working with these species due to their similar characters and appearance (George Cline, pers. comm.). For example, the costal grooves are quite similar in that *E. tynerensis* have 19 to 21 and *E. multiplicata* have 19 or 20. The presence of external gills and the absence of V-shaped markings down the salamander's back have proved to be inadequate characters for distinguishing *E. tynerensis* from larval *E. multiplicata*. Larval *E. multiplicata* have external gills and do not develop their V-shaped markings until they transform into adults. Our specimens from Cucumber Creek also demonstrated characters of *E. tynerensis*, including whitish spots down the sides of the back, a light unmarked belly, and a distinct high tail fin (Black and Sievert 1989, A Field Guide to Amphibians of Oklahoma. Publ. Oklahoma Dept. Wildlife Conservation, Oklahoma City. 80 pp.). However, larval *E. multiplicata* also demonstrate these characters.

Tumlison et al. (1990, Copeia 1990:242–246) described a canonical discriminant function in which the mean canonical discriminant scores for *E. tynerensis* and *E. multiplicata* were 2.38 and –2.58, respectively. Thus, the discriminant function was used to separate *E. tynerensis* and *E. multiplicata* by yielding a discriminant score of >0.0 or <0.0, respectively. Tumlison examined one of our specimens and found the canonical discriminant score to be quite intermediate (i.e., –0.132) compared to his earlier observations. However, the negative discriminant score, smaller tail fin, and general impression of greater robustness point toward *E. multiplicata* as the more likely identification.

Submitted by **WILLIAM I. LUTTERSCHMIDT**, Department of Biological Science, Sam Houston State University, Huntsville, Texas 77341, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: TENNESSEE: Fentress Co: Pickett State Park, ca. 3 km west Tennessee Rt. 154 along road following SW boundary of park (36°32'N, 84°49'W). 23 November 1994. Vincent A. Cobb and Lisa M. Cobb. Austin Peay State University Museum of Zoology (APSU 5689—color slides). Verified by A. Floyd Scott. Individual was found under fallen log ca. 100 m NE of park boundary road. Specimen was not proximate to an immediate water source although Thompson Creek was within a few hundred meters. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94).

Submitted by **VINCENT A. COBB**, Department of Biology, Northeastern State University, Tahlequah, Oklahoma 74464, USA (e-mail: cobbva@nsuok.edu), and **LISA M. COBB**, Division of Math and Science, Connors State College, Warner, Oklahoma 74469, USA.

NECTURUS MACULOSUS (Common Mudpuppy). USA: ILLINOIS: Pulaski Co: unnamed tributary of the Ohio River. 1 April 2001. W. J. Poly and J. E. Wetzel. Illinois Natural History Survey (INHS 17077). Verified by C. A. Phillips. One subadult was collected and preserved (82 mm SVL, 125 mm TL, live weight: 10.9 g). The stream is adjacent to a public boat launch (Caledonia Landing) in the town of Olmsted at Ohio River RM 965 (NW 1/4 NE 1/4 Sec. 26, T15S, R1E) (37°10'47" 89°04'18"), USGS 7.5' Olmsted, Illinois-Kentucky topographic map). This salamander has not been reported previously from Pulaski County (Phillips et al. 1999, Illinois Nat. Hist. Surv. Manual 8: xv + 282 pp.), although it has been collected from adjacent Massac County. Specimen was captured with a seine ca. 50 m upstream from the mouth. At the capture site, stream substrate was primarily mud with some woody debris, and stream banks were steep and muddy. The ventral surface of the specimen is lacking pigment almost entirely, and tips of toes are white. A liver sample was removed and sent to Henry L. Bart, Jr. (Tulane University).

Submitted by **WILLIAM J. POLY** and **JAMES E. WETZEL**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901-6501, USA.

ANURA

BATRACHYLA TAENIATA. ARGENTINA: CHUBUT: DEPARTAMENTO FUTALEUFÚ: Los Alerces National Park, S shore Cisne River at its terminus in Menéndez Lake, 42°37'S, 71°54'W, ca. 525 m. 17 January 1995. Carmen Úbeda. Juvenile specimen (SVL 20 mm). Fundación Miguel Lillo, Tucumán, Argentina (FML 09864, color slide). Verified by Néstor G. Basso. Specimen was found in an evergreen temperate rain forest. *Batrachyla taeniata* inhabits austral forests of Chile and Argentina and Chilean Mediterranean sclerophyllous bushes and forests, with a narrow distributional area at the eastern slopes of the Andes Mountains. In Chile, this frog is distributed from the relictual forests of Zapallar and Quintero (32°34'S, 71°28'W) (Sallaberry et al. 1981, Bol. Mus. Nac. Hist. Nat. Chile 38:61–67) to Laguna San Rafael (46°40'S, 74°00'W) (Díaz-Páez and Williams 1999, Res. V Congr. Latinoamericano de Herpetología. Publ. Extra Museo Nacional de Historia Natural, Montevideo, Uruguay 50:54). In Argentina, it has been recorded from Hua Hum, Neuquén Province (40°07'S, 71°40'W) (Gallardo 1962, Rev. Mus. Argentina Cienc. Nat., Bs. As., Cienc. Zool. 8[10]:113–122) to (without coordinate precision) "the lower Province of Río Negro alongside the austral *Nothofagus* forests" (Cei 1980, Amphibians of Argentina. Monit. zool. ital. (N.S.), Monogr. 2: [i-xii] + 1–609). This voucher represents a new record for the province of Chubut and extends known range of species in Argentina ca. 71 km airline S from southern limit of Río Negro Province. Further, this record decreases the hiatus between the distribution in Chile and Argentina. The area where this specimen was found is also inhabited by the frogs *Batrachyla antartandica*, *Pleurodema thaul*, *Eupsophus calcaratus*, and *Alsodes australis*.

Submitted by **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, R 8400 FRF Bariloche, Provincia de Río Negro, Argentina.

BUFO AMERICANUS (American Toad). USA: TEXAS: Franklin Co: 8.2 mi N jct. Rt. 67/FM 1896, ca. 2 mi W on White Oak Creek Ranch. 29 April 2000. Brian Fontenot. TCWC 84247. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA.

BUFO GUTTATUS (Guianan Golden Toad). VENEZUELA: ESTADO APURE: Santa María del Orinoco, ca. 20 km S mouth of Río Cinaruco on the Orinoco River. 21 April 2000. J. C. Paz. Museo de Biología de la Universidad del Zulia (MBLUZ A- 0139). Verified by Andrés Orellana. First state record. Another Amazonian species discovered NW of previous known distribution (Barrio 1998, Acta Biol. Venezuela 18[2]:1–93). The Río Cinaruco apparently constitutes a northern Amazonian reduct into the Llanos ecotone on the northwestern side of the Orinoco River (previously considered a barrier for many species, including amphibians) or is the natural limit for some Amazonian amphibians and reptiles into the Llanos. Northern Amazonian species such as the Bighead Turtle (*Peltocephalus dumerilianus*) (Pritchard and Trebbau 1984, Turtles of Venezuela. Publ. SSAR. 403 pp.), Gladiator Frog (*Hyla boans*) (Arrington and Arrington 2000, Herpetol. Rev 31:170) and Rocky Frog (*Leptodactylus lithonaetes*) (Heyer 1995, Proc. Biol. Soc. Washington 108[4]:695–716) showed similar distributions crossing the Orinoco River and reaching the Cinaruco River to the Northwest.

Submitted by **CÉSAR LUIS BARRIO**, Fundación Andígena, Apartado Postal 210, Mérida 5101-A, Venezuela (e-mail: cesarlba@yahoo.com), **TITO BARROS**, Museo de Biología, Departamento de Biología, Facultad Experimental de Ciencias, La Universidad del Zulia, Apartado 526, 4001, Maracaibo, Estado Zulia, Venezuela (e-mail: trbarros@cantv.net), and **JUAN CARLOS PAZ**, Departamento de Biología, Facultad de Ciencias, La Universidad del Zulia, Maracaibo, Estado Zulia, Venezuela, Apartado Postal 526 (e-mail: j-c1971@hotmail.com).

BUFO REGULARIS (Egyptian Square-marked Toad). EGYPT: NORTH SINAI PROVINCE: ca. 15 km W Al-Arish City (31°05'47"N, 33°40'06"E). 25 October 2000. A. A. Ibrahim. Muséum National d'Histoire Naturelle (MNHN 2000.5140). Verified by I. Ineich. A large female (96 mm SVL) captured at the backyard of a house near Al-Midan Village at 1000 h. Several other toads were also observed in two pools near the house. Probably introduced from the Nile Delta with foodstuff for sheep and goats, such as fresh clover, often coming from Sharqia Province (information from inhabitants), where *B. regularis* occurs. First record for Sinai Peninsula (Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. 11:1–234).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt (e-mail: aibrahim@ismailia.ie-eg.com).

BUFO VALLICEPS (Gulf Coast Toad). USA: TEXAS: BURNET Co: 2 mi SW jct. Co. Rd. 114 and FM 2341, Vol Montgomery Ranch. 15 April 2000. Gage Dayton, Lee Fitzgerald, and Michael Goldstein. TCWC 84174-84176. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **GAGE H. DAYTON** and **LEE A. FITZGERALD**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA, and **MICHAEL I. GOLDSTEIN**, Mendocino Redwood Company, P.O. Box 489, Fort Bragg, California 95437, USA.

CHIRIXALUS VITTATUS (Striped Treefrog). INDIA: ASSAM: Balipara Reserve Forest (92°39'–92°51'E, 26°53'–27°01'N) and Nameri National Park (92°39'–92°55'E, 26°57'–27°03'N). 27 April 2000. S. Sengupta. Arya Vidyapeeth College Museum (AVC 3201, 3204) and Zoological Survey of India, Calcutta (ZSIC A9136), all males. Verified by S. K. Dutta. One specimen was found ca. 28–41 cm up on a fern growing on a bank of a small rivulet; the others were located on a grassy patch on a sandy riverbank ca. 3 m from a waterhole. These sites (ca. 90–100 m elev.) were surrounded by semi-evergreen forests. Species is known from the state of Nagaland, India (Romer 1949, J. Bombay Nat. Hist. Soc. 48:374–

376), and Bhamo Burma, Myanmar (Boulenger 1890, The Fauna of British India, Including Ceylon and Burma. Reptilia and Batrachia. Taylor and Francis. 541 pp). These records extend its range to the northwest by 210 km.

Submitted by **NRIPENDRA K. CHOUDHURY, JAYANTA GOGOI**, and **SAIBAL SENGUPTA**, Zoology Department, Arya Vidyapeeth College, Guwahati 781016, Assam, India (e-mail [SS]: senguptasaibalsen@rediffmail.com).

ELEUTHERODACTYLUS AUGUSTI (Barking Frog). USA: TEXAS: KINNEY CO: Kickapoo Cavern State Park, 38.8 road km N Brackettville on FM 674. 14 June 2000. John H. Malone. TCWC 83949. Verified by James R. Dixon. County record. (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp). Specimen collected during a baseline amphibian and reptile inventory conducted at Kickapoo Cavern State Park. Collected under the authority of TPWD State Park Scientific Study Permit Number 25-00.

Submitted by **JOHN H. MALONE**, Department of Zoology, University of Oklahoma, 730 Van Vleet Oval, Norman, Oklahoma 73019, USA.

ELEUTHERODACTYLUS JUIPOCA. BRAZIL: GOIÁS: Municipality of Silvânia, Floresta Nacional de Silvânia, 16°39'S, 48°36'W, 900 m. 4 April–5 May 1997. R. P. Bastos. Museu Nacional, Rio de Janeiro (MNRJ 26415-416). Verified by U. Caramaschi and C. A. G. Cruz. Previous reported from the vicinity of the type locality in Sousas, Campinas, São Paulo (Frost 1985, Amphibian Species of the World. A Taxonomic and Geographical Reference. Allen Press, Inc., Lawrence, Kansas. vi + 732 pp.). Also, reported from Sierra da Canastra, 20°10'S, 46°30'W, Municipality of São Roque de Minas, Sacramento and Delfinópolis, Minas Gerais 900–1496 m (Haddad et al. 1988, Brasil Florestal 64:9–20) and Morro do Ferro, 21°48'S, 46°35'W, Municipality of Poços de Caldas, Minas Gerais, 700 m (Cardoso et al. 1989, Rev. Brasil Biol. 49 [1]:241–249). First state record; extends known geographical distribution ca. 490 km to the north.

Submitted by **ROGÉRIO P. BASTOS**, Departamento de Biologia Geral, ICB, Universidade Federal de Goiás, Caixa Postal 131, 74001-970 Goiânia, Goiás, Brazil, and **JOSÉ P. POMBAL JR.**, Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Brazil.

ELEUTHERODACTYLUS ORPHNOLAIMUS. PERU: LORETO: Madre Selva II Biological Station, Iquitos region (03'37.175 S, 72'14.873 W, error = 13.5). 1 January 1998. Ruston W. Hartdegen and Matt J. Russell. UTAVC Color Slide 25722). Verified by J. D. Lynch. First report of species from Peru; third known documentation of the species. Previously, reported from Ecuador (Lynch 1979, Proc. Biol. Soc. Washington 83:221; Duellman 1978, Univ. Kansas Nat. Hist. Mus. Misc. Publ. 65:1–352). Specimen was observed in primary forest, oriented vertically on a small palm tree trunk (ca. 30 cm in diameter), 1.5 m above ground. Ambient air temp was 82°F. *E. orphnolaimus* is thought to be primarily a canopy species.

Submitted by **RUSTON W. HARTDEGEN**, Department of Herpetology, Dallas Zoo, 650 South R.L. Freeway, Dallas, Texas 75203, USA (e-mail: ruston17@yahoo.com), and **MATT J. RUSSELL**, 803 Burr Oak Drive, Lewisville, Texas 75067, USA.

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: FLORIDA: FRANKLIN CO: St. George Island, The Plantation, George Mahr Boy Scout Seabase (N29°63.900, W84°91.648) and St. George Island Airport (N29°64.088, W84°91.213). December 2000. K. J. Irwin, L. K. Irwin, Joseph T. Collins, and Nancy K. Weaver. Department of Herpetology, Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas (MHP 6821–22). Verified by Travis W. Taggart. Several adults and subadults found under board and debris piles at both localities. First record for St. George Island and for Apalachicola Bay Barrier Islands (Blaney 1971, Herpetologica 27:406–430; Means 1974, *In* Livingston et al. [eds.], St. George Island: Biota, Ecology, and Management Program for Controlled Development. Rept. Develop. Regional Impact Franklin County Commission).

Submitted by **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us) and **LISA K. IRWIN**, 103 Brooke Drive, Perryville, Arkansas 72126, USA.

HYLA ANCEPS. BRAZIL: PARANÁ: Telêmaco Borba municipality, Monte Alegre farm (24°04'01"S, 50°41'10"W, ca. 760 m). 14 November 2000. R. A Machado and Sérgio Adão Filipaki. Capão da Imbuia Natural History Museum, Curitiba, Paraná, Brazil (MHNCI 3944–45) and Célio F. B. Haddad collection, deposited in Departamento de Zoologia, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil (CFBH 3575). Verified by José Perez Pombal, Jr. Collected at night over leaves in a freshwater swamp (ca. 80 x 50 m) dominated by *Tipha latifolia* (Tiphaceae). Previously known from the states of Rio de Janeiro (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas, 732 pp.), Espirito Santo (Haddad et al. 1995, Herpetol. Rev. 26:207), Minas Gerais (Nascimento and Feio 1999, Herpetol. Rev. 30:49–50), and Bahia (Argolo 2000, Herpetol. Rev. 31:109). First record from the state of Paraná and from southern Brazil; extends known range ca. 750 km airline SW from previously cited southernmost locality at Rio de Janeiro.

Submitted by **REGINALDO ASSÊNCIO MACHADO**, Curso de Pós-Graduação em Zoologia, Depto. de Zoologia, Universidade Federal do Paraná, CEP 81531-990, Caixa Postal 19020, Curitiba, Paraná, Brazil (e-mail: anurans@bol.com.br) and **CÉLIO FERNANDO BATISTA HADDAD**, Departamento de Zoologia, I.B., UNESP, Caixa Postal 199, 13506-900 Rio Claro, São Paulo, Brazil (e-mail: haddad@rc.unesp.br).

HYLA BOANS (Giant Gladiator Treefrog) VENEZUELA: ESTADO BARINAS: creek without name in Sector Miraflores, Barinitas. 17 December 2000. Markus Vogt. Colección de Vertebrados, Universidad de los Andes, Facultad de Ciencias (CVULA IV-6294). Verified by Daniel Calcaño. First state record. As has been updated by Barrio (1999, Herpetol. Rev. 30:230), species is known to be widely distributed through the Amazonian basin and lowlands of the Guianan Shield in Venezuela, as well as in the Orinoco Delta, appearing as a characteristic element in the Amazonian rainforests. Barrio (*op. cit.*) showed a broad distribution in the country, expanding its distribution to the Amazonian

reduct in Andean foothills of the Estado Táchira. With this new finding, ca. 210 km NE of the Táchira location, it is conceivable that the Amazonian region reaches the Barinas foothills as well, and the possibility that more Amazonian elements will be founded in that Venezuelan state.

Submitted by **CÉSAR LUIS BARRIO AMORÓS**, Fundación ANDÍGENA, Apartado 210, 5101-A Mérida, Venezuela (e-mail: cesarlba@yahoo.com).

HYLA CALCARATA. VENEZUELA: ESTADO BOLIVAR: Estación Biológica Dedemay, Río Tabaro, tributary to Río Caura, 6°21'18"N, 64°59'48", 120 m. 24 April 1995. César Molina. Museo de Historia Natural La Salle, Caracas, Venezuela (MHNLS 14723–24). Verified by Celsa Señaris. In Venezuela, this species is restricted to the upper Orinoco River in the state of Amazona (Duellman 1973, Copeia 1973:515–533; La Marca 1992, Catálogo Taxonómico y Biogeográfico de las Ranas de Venezuela. Cuadernos Geográficos Universidad de Los Andes, Merida, N° 9). Recently, this treefrog was reported in the adjacent state of Bolívar at two localities: Cara Sur del Cerro Guaiquinina and Río Aguas Negras, sur del Cerro Santa Rosa (Barrios 1998, Acta Biol. Venezuelica 18:1–93); however, these records were based on field observations only. These specimens, which represent the first vouchers, were collected at night, calling on a vine, four meters from the forest floor, along a small stream.

Submitted by **CÉSAR R. MOLINA R.**, Museo de Historia Natural La Salle, Apartado Postal 1930, Caracas 1010-A, Venezuela (e-mail: crmolina@mixmail.com).

HYLA CINEREA (Green Treefrog). USA: TEXAS: Milam Co: 5.4 mi E jct. FM 2095 on US Rt. 79. 1 May 2000. Toby J. Hibbitts, Ryan E. Nelson, and Wade A. Ryberg. TCWC 84243. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **TOBY J. HIBBITTS**, **RYAN E. NELSON**, and **WADE A. RYBERG**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA.

HYLA NAHDERERI. BRAZIL: PARANÁ: São José dos Pinhais Municipality (25°41'S, 49°03'W, ca. 1020 m). 31 October 1999 (2000 h). C. E. Conte. Célio F. B. Haddad Collection, deposited in Departamento de Zoología, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil (CFBH 3561). Verified by Paulo C. Garcia. Found at night in low vegetation bordering a lake near disturbed mixed temperate rainforest. First state record for the species; previously known for Serra do Mar from state of Santa Catarina, Brazil, site of the type locality (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.). Extends known range of species in Brazil ca. 70 km airline NNE from previously cited northernmost locality at the São Bento do Sul Municipality, state of Santa Catarina.

Submitted by **REGINALDO ASSÊNCIO MACHADO**, Curso de Pós-Graduação em Zoologia, Departamento de Zoologia, Universidade Federal do Paraná, CP 19020, CEP 81531-990, Curitiba-PR, Brazil (e-mail: anfibios@bio.ufpr.br) and **CARLOS EDUARDO CONTE**, Pontificia Universidade Católica do Paraná, CP 16210, CEP 81611-970, Curitiba-PR, Brazil (e-mail: kaduconte@zipmail.com.br).

HYLA SOARESI. BRAZIL: GOIÁS: Municipality of Mambaí (14°29'S, 46°06'W), 709 m. 3 March 2001. R. F. Juliano and R. Lingnau. Museu Nacional, Rio de Janeiro (MNRJ 26417). Verified by U. Caramaschi and C. A. G. Cruz. Previously recorded from the states of Piauí (Picos), Ceará (Santana do Cariri), Paraíba (Areia Branca), and Minas Gerais (Manga) by Gomes and Peixoto (1996, Iheringia ser. Zool. 80:33–38) and Bahia (Jandaíra) by Gomes and Peixoto (1991, Acta biol. Leopoldensia 13:141–162). First state record, extends the known geographical distribution in approximately 270 km to west.

Submitted by **RAFAEL F. JULIANO**, **RODRIGO LINGNAU**, and **ROGÉRIO P. LITHODYTES LINEATUS: VENEZUELA: ESTADO TRUJILLO: La Gira, Betijoque, ca. 700 m elev. 15 December 1990. Tito Barros. Museo de Biología de la Universidad del Zulia (MBLUZ A-074). ESTADO ZULIA: Yegbashí (aldea indígena Barí), Municipio Machiques de Perijá, Aricuaizá River, Sierra de Perijá, 800 m elev. 28 March 1987. A. Viloria. MBLUZ A-027. Hacienda Puerto Nuevo on the way to El Chorro, Municipio Rosario de Perijá, Sierra de Perijá, 400 m elev. 18 March 2000. E. Arrieta. MBLUZ A-137. Sector La Orchila on the way to La Carpa, Municipio J. E. Lozzada, Sierra de Perijá, 300 m elev. 24 April 2000. E. Arrieta. (MBLUZ A-140). First state records. All verified by Andres Orellana. *Lithodytes lineatus* is a distinctive leptodactylid frog showing a wide distribution in Amazonian lowlands (Lynch 1979, *In* Duellman [ed.], The South American Herpetofauna: its Origin, Evolution, and Dispersal. Mus. Nat. Hist. Univ. Kansas Monogr. No. 7, pp. 189–215). Recently, Barrio (1999, Herpetol. Rev. 30:50) extended its distribution in Venezuela to the Táchira Amazonian reduct. Here, we provide the first evidence that this species also inhabits rainforests in the Perijá and Cordillera de Mérida piedmonts on both Andean slopes of the Maracaibo lake basin, from 300 to 800 m elev., outside of the Amazonian basin. We anticipate its discovery in the Maracaibo Lake Basin piedmont of the states of Mérida and Táchira.

MANTELLA NIGRICANS. MADAGASCAR: ANTSIRANANA: Réserve Spéciale de Manongarivo (14°0.0'S, 48°25.7'E), 14.5 km SW Antanambao village, 1240 m. 7 March 1999. S. M. Goodman. Université d'Antananarivo, Département de Biologie Animale (UADBA 12144; SVL 24.1 mm). Extends range 140 km west from the nearest known locality in the massif of Anjanaharibe-Sud in northeastern Madagascar (Vences et al. 1999, Alytes 17:3–72). First record of a species of the *Mantella cowani* group from northwestern Madagascar. Collected in primary montane forest. Specimen was found active during the day on forest floor in a relatively flat area in open understory not far from a stream. Unequivocally identified as *Mantella nigricans* based on the presence of greenish round flank blotches, lack of a horseshoe marking on throat, ventral black color with about 30 small light round markings on throat, belly, and femurs, lack of reddish or orange ventral color on femurs or tibiae, and lack of rostral stripe. Not conspecific with the types of *Phrynomantis maculatus* (synonym of *Mantella baroni*), which erroneously were quoted to originate from Nosy Be in NW Madagascar (Blommers-Schlösser and Blanc 1991, Faune de Madagascar 75:1–379), and which differ from the characteristics listed above.

The rainforest of Manongarivo was until very recently connected with northeastern forest blocks including Marojejy and Anjanaharibe-Sud (both populated by *M. nigricans*) and are regarded as an extension of this forest type to the Malagasy west coast. To the northeast, Manongarivo is connected to the Tsaratanana Massif, where this species has not yet been found. The forests of northwestern Madagascar, including the Manongarivo Massif, contain a flora that is different in composition than areas to the north or south, and is often considered a different phytogeographic region, the Sambirano. In the original definition of the Sambirano Domain by Perrier de la Bâthie (1921, La végétation malgache, Ann. Mus. Colon. Marseille série 3. 9:1–268), this domain included the lowland forest zone below 800 m. More recent botanical inventories along different slopes of the Manongarivo Massif indicate that the zone of transition between the distinct Sambirano flora and that with affinities to the Central Domain occurs at a higher elevation (around 1200 m) (Messmer et al., *in press*, *In* Gautier and Goodman [eds.], Inventaire floristique et faunistique de la Réserve Spéciale de Manongarivo, Madagascar, Boissiera) or just slightly below where our specimen of *M. nigricans* was collected.

The presence of *Mantella nigricans* and other amphibian species across the zone of mid-altitude forest from northeastern to northwestern Madagascar, but not in lowland forests of the Sambirano, supports the recognition of this domain based on faunistic distributions. Further, the lowland forests of this region hold several species not known to occur at higher elevations (e.g., *Boophis jaegeri, Boophis andreonei, Mantidactylus massi*).

TESTUDINES

ACANTHOCHELYS PALLIDIPECTORIS (Chaco Sideneck Turtle). ARGENTINA: Santa Fe: San Cristóbal Department: captured on a dirt road near Aguará Grande at 30°00'S, 60°45'W. 10 January 2001. A. Larriera and C. I. Piña. Herpetological Collection of Centro de Investigaciones Científicas y Transferencia de Tecnología a la Producción, Diamante, Entre Ríos, Argentina (DIAM-R 0010, photographs) and Herpetological Collection Fundación Miguel Lillo, Tucumán, Argentina (FML 10109, photographs). Verified by M. Cabrera and P. Beldomenico. First department record (Cabrera 1998, Las Tortugas Continentales de Sudamérica Austral. Edic. Indep., Córdoba. 108 pp.). One adult female (CCL 18 cm, SCL 17 cm, PL 15 cm, W 550 g). We have used photographs because the species is listed as 'rare' (Fundación Vida Silvestre, Bertonatti 1994, Cuad. Herpetol. 8:164–171) and 'vulnerable (VU - A1c, D1)' (Hilton-Taylor [compiler] 2000, 2000 IUCN Red List of Threatened Species. IUCN/SSC Gland, Switzerland and Cambridge, United Kingdom]. Extends the known distribution of *A. pallidipectoris* 70 km SW from the city of Calchaquí, Santa Fe.

Submitted by **CARLOS I. PIÑA**, C.I.C. y T.T.P. - CONICET, Dr. Matteri y España, Caixa Postal 3105, Diamante, Entre Ríos, Argentina (e-mail: cidcarlos@infoshopdte.com.ar) and **ALEJANDRO LARRIERA**, Proyecto Yacaré, Bv. Pellegrini 3100, Caixa Postal 3000, Santa Fe, Argentina (e-mail: yacare@arnet.com.ar).

APALONE SPINIFERA HARTWEGI (Western Spiny Softshell). USA: OKLAHOMA: Woodward Co: two male specimens (1 adult, 1 juvenile) observed in Travertine Creek, 7.3 km S and 7.8 km W Freedom. 21 May 2000. Richard L. Lardie. Saint Gregory's University, Shawnee, Oklahoma (SGU Color Slides S9-S12). Specimens were also videotaped. Verified by Doyle L. Crosswhite. County record, 31.3 km NW of nearest record at 2.5 mi W Waynoka, Major County (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press. 370 pp.) and verifes previous sight record (Secor and Carpenter 1984, Okla. Herpetol. Soc. Spec. Publ. 3:1–57). Also helps fill distribution gap with more westerly records in Beaver, Texas, and Cimarron counties (Webb 1970, *op. cit.*) in Oklahoma Panhandle, and Wheeler and four other Texas Panhandle Counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: ILLINOIS: Rock Island Co: Milan (Sec 23, T17N, R2W). 4 June 1957. Gene Forett. HDW-NIU 1709–1710 (formerly RE 228, Putnam Museum of History and Natural Sciences, Davenport, Iowa). Verified by Christine Chandler. Validates a previous record cited without a voucher specimen by Cahn (1937, Illinois Biol. Monog. 16:1–218 and Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: NEW MEXICO: Santa Fe Co: city of Santa Fe, Santa Fe Country Club golf course on Airport Road. 26 October 2000. Isaac Medina. KU Color Slide 11821. Verified by Charles W. Painter. First record for county (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.). Occurrences within the city of Santa Fe (and the Santa Fe River drainage system) are likely the result of introductions.

However, a native population is expected to occur within the county in the Rio Grande, ca. 30 km NW of the city.

Submitted by **JAMES N. STUART**, New Mexico Department of Game and Fish, Conservation Services Division, Santa Fe, New Mexico 87504-5112, USA.

EMYDOIDEA BLANDINGII (Blanding's Turtle). USA: MISSOURI: Holt Co: Squaw Creek National Wildlife Refuge. Three specimens: 1) NE 1/4 Sec. 23, T61N, R39W. 2 October 2000. Male, 10+ years, weight 1447 g. Marked with hole drilled through left marginal scite no. 12. Jacob L. Lehemer. 2) NW 1/4 Sec. 19, T61N, R39W. 17 October 2000. Male 11+ years, 1930 g. Marked with a hole drilled through left marginal scute no. 10. Francis E. Durbian. Verified by Tom R. Johnson. KU color slide 11820. 3) One specimen was captured and released from this site on 13 October 1984 and no population had been verified for this site since that time of capture (Johnson 2000, The Amphibians and Reptiles of Missouri. Second Ed. Missouri Dept. Conserv., Jefferson City. 400 pp.).

Submitted by **FRANCIS E. DURBIAN**, **JACOB L. LEHMER**, Squaw Creek National Wildlife Refuge, P.O. Box 158, Mound City , Missouri, 64470-0158, USA, and **JEFFREY T. BRIGGLER**, Missouri Department of Conservation, P.O. Box 180, Jefferson City, Missouri, 65102, USA.

PSEUDEMYS CONCINNA (Eastern River Cooter). USA: LOUISIANA: Vernon Parish: 5 mi E Pickering, near jct. Rts. 10 and 467. 5 July 2000. Beau B. Gregory. Seale Museum of Louisiana, McNeese State University (SML 9325). Verified by Steve Shively. First Parish record; extends distribution N from Beauregard Parish and W from Rapides Parish as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana State University Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA, and **BEAU B. GREGORY**, Environmental and Natural Resources Management Division, Directorate of Public Works, Fort Polk, Louisiana, 71459, USA.

PSEUDEMYS CONCINNA (Eastern River Cooter). USA: MISSOURI: St. Charles Co: backwater of Mississippi River on Portage Island (T48N, R6E). 8 August 2000. Eric Ratcliff and Eric J. Gittinger. Illinois Natural History Survey (INHS 16207). Verified by C. A. Phillips. New county record and northernmost record in Mississippi River drainage (Johnson 2000, The Amphibians and Reptiles of Missouri. Second Ed. Missouri Dept. Conserv., Jefferson City. 400 pp.). Specimen collected in fyke net set inside backwater.

Submitted by **JOHN K. TUCKER**, **ERIC RATCLIFF**, and **ERIC J. GITTINGER**, Illinois Natural History Survey, Great Rivers Field Station, 8450 Montclaire Avenue, Brighton, Illinois 62012, USA, and **J. BRIAN TOWEY**, Department of Zoology, Eastern Illinois University, Charleston, Illinois 61920, USA.

PSEUDEMYS CONCINNA METTERI (Missouri River Cooter). USA: TEXAS: Cass Co: 8 km N Queen City off US Rt. 59 at FM 2327. 10 May 2001. Chris T. McAllister. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26090). Verified by Stanley E. Trauth. New county record that helps fill a spotty geographic distribution in northeastern Texas (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **CHRIS T. McALLISTER**, Department of Biology, Texas A&M University at Texarkana, Texarkana, Texas 75505, USA.

PSEUDEMYS GORZUGI (Western River Cooter). USA: Texas: Menard Co: ca. 9 mi W Menard. 31 August 1998. Carl J. Franklin and Richard D. Reams. Adult male basking on the shoulder of Texas Rt. 190. UTACV R 46050. Verified by Jonathan A. Campbell. New county record; suggests that *Pseudemys texana* and *P. gorzugi* are sympatric in portions of their range and that *P. gorzugi* has a wider distribution than previously thought. Extends range ca. 170 km NE of the nearest previously documented locality in Del Rio, Texas (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **CARL J. FRANKLIN**, 1001 Denmark Drive Grand Prairie, Texas 75050, USA (e-mail: herpking@ix.netcom.com), and **RICHARD D. REAMS**, 1402 Ramses Avenue, Dallas, Texas 75216, USA (e-mail: hylareams@aol.com).

PSEUDEMYS NELSONI (Florida Redbelly Turtle). USA: FLORIDA: Franklin Co: St. Vincent Island, St. Vincent National Wildlife Refuge, Rattlesnake Slough at Oyster Pond, (N29°64.383, W85°14.850). 5 August 2000. T. E. Lewis and L. K. Irwin. Department of Herpetology, Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas, (MHP 6812). Verified by Joseph T. Collins. Carcass found in dry pond bottom. First record for St. Vincent Island and first record for Apalachicola Bay Barrier Islands (Blaney 1971, Herpetologica 27:406–430; Christman 1984, Natural History of St. Vincent Island, Florida. Progress Report No. 1, Covering the Period January 1983–December 1983. Unpubl. Report to Denver Wildl. Res. Center, Ecol. Section, Gainesville, Florida. 25 pp.).

Submitted by **THOMAS E. LEWIS**, St. Vincent National Wildlife Refuge, P.O. Box 447, Apalachicola, Florida 32329, USA, **LISA K. IRWIN**, 103 Brooke Drive, Perryville, Arkansas 72126, USA, and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us).

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). USA: TEXAS: Franklin Co: 8.2 mi N jct. Rt. 67/FM 1896, ca. 2 mi W on White Oak Creek Ranch. 29 April 2000. Toby J. Hibbitts. TCWC 84265–66. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA.

LACERTILIA

ANOLIS AURATUS (Grass Anole). VENEZUELA: ESTADO ANZOATEGUI: Campamento El Caiman del Orinoco, 17 km NE

Soledad (8°09'N, 63°32'W, 50 m). 26 October 2000. Paul M. Kornacker. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 73928). Verified by César Molina. First state record. Nearest known records are from Guri, Estado Bolivar, 80 km S of Orinoco River (Donoso-Barros 1968, Carib. J. Sci. 8[3–4]:105–122; Gorzula and Señaris 1998, Contribution to the Herpetofauna of the Venezuelan Guayana. Scientia Guainae, Caracas. 269 pp.; Kornacker and Meyer zur Heyde 1998, Herpetologische Eindrücke einer Venezuelareise. Teil 3: El Embalse de Guri - der Guri-Stausee. Elaphe 6[4]:61–69).

ANOLIS CAROLINENSIS (Green Anole). ANGUILLA: Shoal Bay Village. 24 June 2000. James M. Eaton and Kathrine G. Howard. Bobby Witcher Memorial Collection, Avila College (BWMC 06787, adult female; BWMC 06792, adult male). Verified by Robert W. Henderson. First records for the island and for the West Indies (published accounts of *A. carolinensis* in the Bahamas undoubtedly refer to *A. smaragdinus*). Like *Osteopilus septentrionalis*, now firmly established on Anguilla (Townsend et al. 2000, Carib. J.. Sci. 35: *in press*), these anoles most likely were brought to Anguilla in containers of plants from southern Florida used for landscaping purposes, especially in resort areas. We heard anecdotal accounts of "green tree lizards" from employees of several resorts, but did not find specimens at sites other than Shoal Bay Village. Although *Anolis carolinensis* is not known as a particularly effective colonizer (Losos and Spiller 1999, Ecology 80:252–258), it could become a permanent and visible component of the Anguillian herpetofauna because of three important factors that predispose it to success: 1) these anoles probably were accompanied on arrival by plants with which they were already associated; 2) although the island is xeric, suitable mesic habitat on Anguilla is available in resort areas; and 3) *A. carolinensis* is unlikely to compete directly with native *A. gingivinus*.

ANOLIS CAROLINENSIS (Green Anole). USA: TEXAS: Franklin Co: 8.2 mi N jct. Rt. 67/FM 1896, ca. 2 mi W on White Oak Creek Ranch. 29 April 2000. Toby J. Hibbitts. TCWC 84251. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA.

ANOLIS CAROLINENSIS (Green Anole). USA: TEXAS: Medina Co: 12.39 road km W Bexar County line. July 2000. R. Michael Burger. University of Texas at Arlington (UTA Color Slides 25765-66). Verified by J. A. Campbell. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp).

Submitted by **R. MICHAEL BURGER**, Department of Herpetology, Dallas Zoo, 650 South R.L. Thornton Fwy (I-35), Dallas, Texas 75203, USA.

EUMECES LATICEPS (Broadhead Skink). USA: TEXAS: Franklin Co: 8.2 mi N jct. Rt. 67/FM 1896, ca. 2 mi W on White Oak Creek Ranch. 29 April 2000. Terry L. Hibbitts. TCWC 84250. Verified by James R. Dixon. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, 210 Nagle Hall, College Station, Texas 77843-2258, USA, and **TERRY L. HIBBITTS**, 602 Hilltop Circle, Wylie, Texas 75098, USA.

EUMECES SKILTONIANUS (Western Skink). USA: ARIZONA: Mohave Co: Arizona Strip District, Mount Logan, N of Colorado River, N36°214.488', W113°104.254'. 12 June 1998. Stephen S. Germaine, Heather L. Germaine, and Hans F. Koenig. UAZ 50930-PSV. Verified by Philip C. Rosen. Two adult specimens (6.8–7.0 cm SVL) were collected under decaying logs at ca. 2160 m. The habitat was open Ponderosa Pine-Gambel Oak forest with understory vegetation dominated by sagebrush, *Artemisia*. One specimen deposited five eggs on 4 July 1998. Eggs ranged from 5.4 to 6.5 mm in length, and hatched 11 August 1998 after incubation at 26–27°C. A review of museum specimens revealed one other individual collected on Mount Logan, ca. 2400 m on 18 July 1974 by M. D. Robinson (UAZ 40316). Species was previously known from the North Kaibab Plateau, Big Springs, Coconino County, Arizona (N36°36.07', W112°20.57'. 28 August 1939. D. O. Scott. SDNHM 32548). The Mt. Logan locality extends the range of this lizard ca. 79 km.

Submitted by **HANS F. KOENIG**, Arizona Game and Fish Department, P.O. Box 1269, St. George, Utah 84771, USA, and **STEPHEN S. GERMAINE** and **HEATHER L. GERMAINE**, Arizona Game and Fish Department, 2222 West Greenway Road, Phoenix, Arizona 85023, USA.

HEMIDACTYLUS FRENATUS (House Gecko). BELIZE: ORANGE WALK DISTRICT: on a brick building in Lamanai Field Research Center, Indian Church Village, ca. 150 m west of New River Lagoon (17°45'N, 88°39'W). 19 October 2000. Thomas R. Rainwater. University of Miami Reptile Collection (UMRC 00-002). Verified by Julian C. Lee. District record; fills distribution gap between districts of Corozal and Belize, leaving Toledo as the only district in Belize from which *H. frenatus* has not been confirmed (Stafford and Meyer 1999, A Field Guide to the Reptiles of Belize. Academic Press, New York. 356 pp.).

Submitted by **THOMAS R. RAINWATER**, Lamanai Field Research Center, P.O. Box 63, Orange Walk Town, Belize, and **STEVEN G. PLATT**, Wildlife Conservation Society, P.O. Box 9345, Siem Reap, Cambodia.

HEMIDACTYLUS MABOUIA (Tropical Gecko). VENEZUELA: DISTRITO FEDERAL: Caracas, 900 m elev.. 2 June 1983. F. Provenzano. Museo de Biología, Universidad Central de Venezu-

ela, Caracas (MBUCV 2156, adult male); Urbanización Vista Alegre, calle 7, Caracas, 900 m. 4 October 1992. O. Lasso. Museo de Historia Natural La Salle, Caracas (MHNLS 14188, juvenile). ESTADO VARGAS: Tanaguarenas, 10 m. 4 January 1965. Carlos Galán. MHNLS 1972, adult male. All specimens verified by Enrique La Marca. Extends known distribution of species to coastal area of north-central Venezuela. This taxon was previously known from eastern Venezuela (Rivas and Oliveros 1997, Mem. Soc. Cienc. Nat. La Salle 147:67–80). In Venezuela, *Hemidactylus mabouia* appears to have a broader distribution than previously known.

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Sección de Herpetología, Apartado Postal 1930, Caracas 1010-A, Venezuela; e-mail: gilsonrivas@mixmail.com.

HEMIDACTYLUS PALAICHTHUS. VENEZUELA: ESTADO ANZOATEGUI: Campamento El Caiman del Orinoco, 17 km NE Soledad (8°09'N, 63°32'W, 50 m). 26 October 2000. Paul M. Kornacker. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 73929). Verified by César Molina. First state record. Locality is about 250 km S of the northern population at Península de Paria, Estado Sucre, but only 80 km distant from the locality at Guri-Lake, Estado Bolivar, south of the Orinoco River (Gorzula and Señaris 1998, Contribution to the Herpetofauna of the Venezuelan Guayana. Scientia Guainae, Caracas. 269 pp.).

Submitted by **PAUL M. KORNACKER**, Aachener Strasse 42, D-53359 Rheinbach, Germany; e-mail: pkornacker@aol.com or pakoverlag@aol.com.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: OKLAHOMA: Garfield Co: two adults (one collected live, one found dead) in Mid-Continent Packaging building at 1200 North 54th Street, Enid, Oklahoma. Date unknown. Gloria and Dean Brisson. Saint Gregory's University, Shawnee, Oklahoma collection (SGU 2034–35). Verified by Doyle L. Crosswhite. A second live specimen, a juvenile, was brought to me from the same location. Several others have been observed at this same location. This appears to be the most northerly Oklahoma location reported for this introduced species and is apparently an established, reproducing population. Presumably, this lizard was introduced via trucks from other locations. Species has been reported at locations in Okeene, Blaine County (Mark Howery, Oklahoma Dept. Wildlife, pers. comm.), on the University of Oklahoma campus (OU), Clevland County, Oklahoma Baptist University Campus, Pottawatomie County, and the Univ. Oklahoma Biological Station, Marshall County (Sievert and Sievert 1993, A Field Guide to Reptiles of Oklahoma. Publ. Oklahoma Dept. Wildlife Conservation. 104 pp.). These may also represent the most northerly location reported in North America (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.).

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Collin Co: south-central Plano off Plano Parkway. 26 March 2000. Miguel Sanchez. Navarro College Herpetological Collection 2000. 3. 26. 1L. Verified by Gilbert Gatlin. Juvenile collected in a vegetable garden. New county record; partly fills hiatus of this introduced species in northern Texas range (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **THOMAS VANCE**, Biology Department, Navarro College, Corsicana, Texas 75110, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Medina Co: 12.39 road km W Bexar County line. July 2000. R. Michael Burger. University of Texas at Arlington (UTA Color Slide 25764). Verified by J. A. Campbell. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp).

Submitted by **R. MICHAEL BURGER**, Department of Herpetology, Dallas Zoo, 650 South R.L. Thornton Fwy (I-35), Dallas, Texas 75203, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Taylor Co: 4 km N downtown Abilene, Hardin-Simmons University Greenhouse Building (32°28'41"N, 99°44'02"W). 8 August 2000. Allan J. Landwer. Hardin-Simmons University Collection of Vertebrates (HSUCV 615). Verified by Mark Muhr. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **ALLAN J. LANDWER**, Department of Biology, Hardin-Simmons University, Abilene, Texas 79698-6165, USA (e-mail: alandwer@hsutx.edu) and **THOMAS E. LEE, JR.**, Department of Biology, Abilene Christian University, Abilene, Texas 79699-7868, USA (e-mail: leet@nicanor.acu.edu).

HEMIPHYLLODACTYLUS TYPUS (Indo-Pacific Tree Gecko). THAILAND: PHUKET PROVINCE: Kata District: Kata View Point on Road 4233 between Ban Kata (7°49'N, 98°19'E) and Ban Sai Yuan. 3 September 1997. O. S. G. Pauwels. Institut Royal des Sciences naturelles de Belgique (IRSNB 15501). Verified by Ned Gilmore. A single specimen was collected in late afternoon on rocks along the road in strict syntopy with numerous *Hemidactylus frenatus* (IRSNB 15503–10) and a single juvenile *Cosymbotus platyurus* (IRSNB 15502). This specimen represents the first record for both Phuket Island and the Province. The closest known locality is Boi Yai Island in Phang-Nga Province (Pauwels et al. 2000, Dumerilia 4:123–154), situated 45 airline km to the northeast. The species was first recorded from Thailand (as *Lepidodactylus ceylonensis*) by Smith and Kloss (1915, J. Nat. Hist. Soc. Siam 1:337–348), who found a single specimen at Klong Menao (15 mi NW Klong Yai, Trat Province). Taylor (1963, Univ. Kansas Sci. Bull. 44:687–1077) included this species in the Thai fauna, but collected no material himself. The Phuket record appears to be only the third published record of *H. typus* from Thailand.

Submitted by **OLIVIER S. G. PAUWELS**, Department of Recent Vertebrates, Institut Royal des Sciences naturelles de Belgique, Rue Vautier 29, 1000 Brussels, Belgium (e-mail: osqpauwels@hotmail.com) and **AARON M. BAUER**, Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA (e-mail: aaron.bauer@villanova.edu).

HOMONOTA ANDICOLA. ARGENTINA: CATAMARCA: Tinogasta Department: 240 km from city of Catamarca on Chaschuil, Valle de Chaschuil (27°30'S, 70°16'W) 13 January 2001. Juan Carlos Acosta, Graciela Blanco and Juan Manuel Acosta. Herpetological Collection. Instituto y Museo de Ciencias Naturales, Universidad Nacional de San Juan, Argentina (IMCN-UNSJ 500–510). Verified by Ricardo Martori. First record for Catamarca Province; extends known range (Torres et al. 1997, Herpetol. Rev. 28:96) ca. 110 km N of nearest locality (Las Chacritas, Alto Jagüe, General Lamadrid Department, La Rioja Province).

Submitted by **JUAN CARLOS ACOSTA** and **GRACIELA BLANCO**, Departamento de Geofísica y Astronomía e Instituto y Museo de Ciencias Naturales, F.C.E.F. y N., Universidad Nacional de San Juan, Avenida España 400 (N) C.P. 5400, San Juan, Argentina; e-mail (JCA): jcacosta@sinectis.com.ar.

LIOLAEMUS LINEOMACULATUS. ARGENTINA: CHUBUT: on Rt. 37, 8 km W jct. Rts. 37 and 3, 45°37'S, 67°42'W, ca. 2150 m. 25 January 2000. Jim Schulte II and Nora Ibargüengoytía. Herpetological Collection Museo de La Plata, Buenos Aires province, Argentina (MLP.S. 2106); on the shore of Aleusco Lake, 43°05'S, 70°26'W, ca. 620 m. 23 November 2000. G. Amico and L. Sympson. MLP.S. 2107. RÍO NEGRO: 2 km from Seccional Ñirihuau, on SE shore of the Ñirihuau river, 41°18'S, 71°15'W, ca. 1150 m. 26 January 2000. G. Amico and L. Sympson. MLP.S. 2108. All specimens verified by J. M. Cei. *Liolaemus lineomaculatus* has been known from Santa Cruz and Chubut provinces. The northernmost locality is at the west corner of Chubut (44°51'S, 71°40'W) at 980 m. (Williams 1997, Cuad. Herpetol. 11:88–89). A population, probably referable to *L. lineomaculatus*, was found associated with the *Araucaria* forest in Primeros Pinos, Neuquén Province (Cei 1986, Museo Regionale di Scienze Naturali, monografia IV. Torino, Italy. 528 pp.). These specimens represent the second record for Chubut and the first record for Río Negro Province, and represent a link between the Chubut and Neuquén populations. The present data extend the known distribution of this species ca. 360 km north from previously known localities.

Submitted by **NORA IBARGÜENGOYTÍA** and **LAURA M. CASALINS**, Centro Regional Universitario Bariloche, Universidad Nacional del Comahue, Provincia de Río Negro, Argentina, **JAMES A. SCHULTE II**, Campus Box 1137, Department of Biology, Washington University, St. Louis, Missouri 63130-4899, USA, **GUILLERMO C. AMICO**, Centro Regional Universitario Bariloche, Universidad Nacional del Comahue, Provincia de Río Negro, Argentina, and **LORENZO SYMPSON**, Km 14, Bustillo, Bariloche, Provincia de Río Negro, Argentina.

MICROLOPHUS THERESIOIDES. CHILE: II REGION DE ANTOFAGASTA: Provincia de Antofagasta, Estación Pampa Unión (23°04'S, 69°30'W), 1413 m. 6 December 2000. J. C. Ortiz, M. Vidal, and M. Hengst. Museo de Zoología de la Universidad de Concepción (MZUC 25814–815). Verified by P. Victoriano. Adults specimens found on *Schinus molle* or among *Atriplex atacamensis*. New country record; extends the southern range of this species on the S Loa River by ca. 55 km from a record at Calama (Ortíz 1980, Actas I Reunión Iberoamericana Zool. Vert., La Rábida, pp. 355–377).

Submitted by **JUAN CARLOS ORTÍZ** and **MARCELA VIDAL**, Departamento de Zoología, Facultad de Ciencias Naturales y Oceanográficas, Universidad de Concepción, Casilla 160-C, Concepción, Chile.

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: OKLAHOMA: Woodward Co: AOR, 7.3 km S and 9.1 km W Freedom. 21 May 2000. Richard L. Lardie. Saint Gregory's University, Shawnee, Oklahoma (SGU Color Slides S9–S12. Verified by Doyle L. Crosswhite. County record; extends range 34.4 km W of the nearest record, 12 mi W Alva, Woods County (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press. 370 pp.) and verifies previous sight record (Secor and Carpenter 1984, Oklahoma Herpetol. Soc. Spec. Publ. 3:1–57). Specimen was one of two observed on the road 1.3 km W Travertine Creek. Videotape records were also made of both specimens.

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

PTYODACTYLUS HASSELQUISTII HASSELQUISTII (Fantoed Gecko). EGYPT: NORTH SINAI PROVINCE: Zaranik Protected Area, Sebeeka (31°04'18"N, 33°27'55"E). 11 August 2000. A. A. Ibrahim. The Hebrew University of Jerusalem (HUJ-R 19411-13). Verified by Y. L. Werner. Found in salt factory buildings. Several individuals were also observed in old railway station buildings ca. 20 m from the factory. Six yellowish-white eggs were seen adhering to the ceiling corners, and at the top of the walls in the railway buildings in August. A single individual was also observed in the visitors' center (ca. 430 m from the factory). Old railway buildings in Mazar, west of Zaranik (31°02'36"N, 33°22'56"E), and Midan, E of Zaranik (31°04'35"N, 33°34'51"E) were checked, but the gecko was not found. Individuals in Sebeeka were very pale in color and almost patternless, in contrast to animals in South Sinai Province, which are dark and clearly cross-banded. This may reflect the gecko's ability to change its coloration physiologically, or a consequence of selection on the whitish walls of the factory and railway buildings. In North Sinai Province, the species was considered replaced by *P. guttatus* (Werner and Sivan 1993, Rev. Esp. Herpetol. 7:47–64). First province record (Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No.11:1–234).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt; e-mail: aibrahim@ismailia.ie-eg.com.

SPHAERODACTYLUS PARVUS (Anguilla Bank Dwarf Gecko). ANGUILLA: Scrub Island, near Scrub Bay. 12 June 2000. Saul S. Nava and Justin J. Shew. Bobby Witcher Memorial Collection, Avila College (BWMC 02634, 06736, 06738). Verified by John S. Parmerlee, Jr. First records for Scrub Island, although this species (formerly considered a subspecies of *S. macrolepis*) is common on nearby Anguilla (Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville).

Submitted by **ALLAN J. LANDWER**, Department of Biology, Hardin-Simmons University, Abilene, Texas 79698-6165, USA (e-mail: alandwer@hsutx.edu) and **THOMAS E. LEE, JR.**, Department of Biology, Abilene Christian University, Abilene, Texas 79699-7868, USA (e-mail: leet@nicanor.acu.edu).

CROTALUS LEPIDUS LEPIDUS (Mottled Rock Rattlesnake). MÉXICO: CHIHUAHUA: Cerros Colorados, 11.2 km NW Ojo Caliente on "Rio Grande Road," Municipio Guadalupe Bravos. 27 July 1975. T. R. Van Devender and B. L. Everitt. Sul Ross State University Vertebrate Collection (SRSU 4815). Verified by James F. Scudday. Third precise state record; extends range ca. 300 air km NW from closest recorded locality in Chihuahua (Lemos-Espinal et al. 2000, Herpetol. Rev. 31:113). Lemos-Espinal et al. (*op. cit.*) reported a specimen of *C. l. lepidus* from La Perla as being the first precise locality of record from Chihuahua; Klauber (1952, Bull. Zool. Soc. San Diego 26:51) reported a specimen (UI 22812) from "15 miles north of Escalón in the southeast corner of Chihuahua."

Submitted by **ROBERT W. BRYSON, JR.**, and **JAMES M. MUELLER**, Department of Biology, Sul Ross State University, Alpine, Texas 79832, USA.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: TEXAS: KINNEY CO: Kickapoo Cavern State Park, 38.8 rd km N Brackettville on FM 674. 14 March 2000. Joel A. Johnson. TCWC 83930. Verified by James R. Dixon. County record. (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp). Specimen collected during a baseline amphibian and reptile inventory conducted at Kickapoo Cavern State Park. Collected under the authority of TPWD State Park Scientific Study Permit Number 25-00.

Submitted by **JOEL A. JOHNSON** and **JOHN H. MALONE**, Department of Zoology, University of Oklahoma, 730 Van Vleet Oval, Norman, Oklahoma 73019, USA.

ELAPHE GUTTATA GUTTATA (Corn Snake). USA: TEXAS: NEWTON CO: ca. 9.7 km NE Burkeville. 27 June 1998. Carl J. Franklin and Richard D. Reams. UTACV R 45194. Verified by Jonathan A. Campbell. Specimen was found DOR on Texas Rt. 63 at 2347 h. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **CARL J. FRANKLIN**, 1001 Denmark Drive, Grand Prairie, Texas 75050, USA (e-mail: herpking@ix.netcom.com), and **RICHARD D. REAMS**, 1402 Ramses Avenue, Dallas, Texas 75216, USA (e-mail: hylareams@aol.com).

ELAPHE OBSOLETA LINDHEIMERII (Texas Rat Snake). USA: TEXAS: GREGG CO: 3.2 km SW Longview off Tex. Rt. 31, Sabine River bottoms. 22 April 2001. Sonny Burns and Josh Kessler. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 25744). Verified by Stanley E. Trauth. New county record. Except for Jack and Rains counties, completely fills distributional hiatus in all of east and central Texas (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.; Werler and Dixon 2000, Texas Snakes: Identification, Distribution, and Natural History. Univ. of Texas Press, Austin. 437 pp.).

Submitted by **JOSHUA E. KESSLER** and **CHRIS T. MCALLISTER**, Department of Biology, Texas A&M University at Texarkana, Texarkana, Texas 75505, USA.

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). USA: ILLINOIS: ROCK ISLAND CO: (Sec. 2, T77N, R2W). 1961. Robert Schroder. HDW-NIU 1745 (formerly RE 22, Putnam Museum of History and Natural Sciences, Davenport, Iowa). Verified by Christine Chandler. New county record; extends range north along the Mississippi River from Hancock County and the disjunct populations in Carroll and Jo Daviess counties (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

ELAPHE OBSOLETA SPILOIDES (Midland Rat Snake). USA: FLORIDA: FRANKLIN CO: St. George Island, The Plantation, St. George Island Airport (N29°64088, W84°91213). 28 December 2000. K. J. Irwin. Department of Herpetology, Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas (MHP 6820). Verified by Lisa K. Irwin. Subadult found at edge of slash pine forest adjacent to airport runway clearing. First record for St. George Island (Blaney 1971, Herpetologica 27:406–430; Means 1974, A Survey of the Amphibians, Reptiles, and Mammals

Inhabiting St. George Island, Franklin County, Florida, with Comments on Vulnerable Aspects of their Ecology. *In* Livingston et al. [eds.], St. George Island: Biota, Ecology, and Management Program for Controlled Development. Rept. Develop. Regional Impact Franklin County Commission).

Submitted by **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA; e-mail: kirwin@agfc.state.ar.us.

HYDROPS TRIANGULARIS. VENEZUELA: PORTUGUESA: Municipio Papelón: Estación Pisciola, Papelón, 8°57'34"N, 69°28'22"W, 69 m. No specific date of collection. Collected by workers at the station. MCNG 1602; Municipio undetermined: Guanare, on road to Barinas. 28 November 1987. B. Busto and C. Ramo. MCNG 1006. Both specimens verified by T. Horger. Second records from west central Venezuela, ca. 140 km SSW of nearest record from the state of Cojedes (Roze 1966, La Taxonomia y Zoogeographia de los Ophidios de Venezuela. Univ. Central de Venezuela, Edic. Biblioteca 28, Caracas. 362 pp.; Rivas and Fuentes 2000, Herpetol. Rev. 31:186).

Submitted by **ALLEN MARKEZICH**, Department of Natural Sciences, Black Hawk College, Moline, Illinois 61265 (e-mail: markezicha@bhc1.bhc.edu).

LAMPROPELTIS MEXICANA (San Luis Potosi Kingsnake). MEXICO: NUEVO LEÓN: 8.6 km E Iturbide on Rt. 58, Municipio Iturbide (24°44'45.5"N, 99°50'61.6"W; 1036 m). 24 July 2000. Gerard T. Salmon, Daniel Vermilya, and Bartholomew B. Bruno. Universidad Autónoma de Nuevo León Herpetological Collection (UANL 5773). Verified by Hobart M. Smith. DOR adult male. Easternmost locality for the species in the state of Nuevo León. Extends reported range ca. 19 air km to the east of TU 16483 (Garstka 1982, Breviora 466:1–35) and to E slope of the Sierra Madre Oriental. Lowest elevation record for the species (Gehlbach 1967, Cat. Am. Amphib. Rept. 55).

Submitted by **GERARD T. SALMON**, 30 Appletree Drive, Rhineback, New York 12572, USA, **ROBERT W. BRYSON, JR.**, Department of Biology, Sul Ross State University, Alpine, Texas 79832, USA, and **DAVID LAZCANO**, Laboratorio de Herpetología, Universidad Autónoma de Nuevo León, Apartado Postal 513, San Nicolas de los Garza, Nuevo León, Caixa Postal 66450, México.

LAMPROPELTIS MEXICANA (San Luis Potosi Kingsnake). MÉXICO: SINALOA: 4 km W El Palmito on Rt. 40, Municipio Concordia (23°33'14.2"N, 105°50'47.2"W, 2000 m). 30 June 2000. Robert Bryson, Deron Hartman, and Javier Banda. Universidad Autónoma de Nuevo León Herpetological Collection (UANL 5684). Verified by Robert G. Webb. DOR juvenile. First state record and westermost locality for species. Extends reported range ca. 95 air km to the west (Webb 1984, *In* Seigel et al. [eds.], Univ. Kansas Mus. Nat. Hist. Spec. Publ. 10:1–278) and ca. 10 air km from a previously unreported specimen of *L. mexicana* (FWMSH 6716) from Durango.

Submitted by **ROBERT W. BRYSON, JR.**, Department of Biology, Sul Ross State University, Alpine, Texas 79832, USA, **GERARD T. SALMON**, 30 Appletree Drive, Rhineback, New York 12572, USA, and **DAVID LAZCANO**, Laboratorio de Herpetología, Universidad Autónoma de Nuevo León, Apartado Postal 513, San Nicolas de los Garza, Nuevo León, Caixa Postal 66450, México.

LIOPHIS COBELLA TAENIOGASTER. BRAZIL: PARÁ: Santarém (54°42'W, 2°26'S), margin of the Tapajós River, Comunidade São Bras. S. Santos. Date and collector unknown. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1555 and 1559). Verified by Rubens N. Yuki. This taxon has been recorded from northeastern Brazil, from Isla Bantanal east to coastal Bahia and north to Rio Amazonas (mainly along the south bank). Specimen represents the westernmost record from the state of Pará and extends the known distribution ca. 240 km to the west (Dixon 1983, J. Herpetol. 17:149–165).

Submitted by **JOSSEHAN GALÚCIO DA FROTA**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200; e-mail: jgfrota@mailbr.com.br.

MALPOLON MONSPESSULANUS INSIGNITUS (Montpellier Snake). EGYPT: NORTH SINAI PROVINCE: Rafah (31°17'32"N, 34°14'26"E). R. M. Ismail and M. K. Hemdan. Muséum National d'Histoire Naturelle (MNHN 2000.5146 and 2000.4289). Verified by I. Ineich. A large female (ca. 983 mm SVL) and a juvenile (ca. 310 mm SVL) captured near the Sinai-Cisjordan border on 15 July and 24 October 2000, respectively. In Egypt, this species was previously known from Port Said and Domyatt (NE Egypt), the western Mediterranean coastal desert, and the Nile Delta (Marx 1968, Checklist of Amphibians and Reptiles of Egypt. Spec. Publ. U.S. Naval Med. Res. Unit No. 3:1–51; Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. 11:1–234). First record for the Sinai Peninsula (Werner 1982, *In* Scott [ed.], Herpetological Communities, pp. 153–161. U.S. Fish and Wildlife Service Wildl. Res. Rep. 13. Washington, D.C.).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt; e-mail: aibrahim@ismailia.ie-eg.com.

MICRURUS FULVIUS TENER (Texas Coral Snake). USA: TEXAS: CASS CO: 4.8 km NW Kildare off FM 125. 9 March 2001. Michael Harp. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 25590); 1.6 km off Texas 59 on county road 3659, vic. Queen City. September 1999. Steve Patterson. ASUMZ 25592 (color print). Both verified by Stanley E. Trauth. New county record and partially fills distributional gap in Arkansas-Louisiana-Texas. Species has been reported previously from NE Texas in adjacent Morris County (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.; Werler and Dixon 2000, Texas Snakes: Identification, Distribution, and Natural History. Univ. Texas Press, Austin. 437 pp.), in SW Arkansas in Lafayette County (Trauth, Robison, and Plummer, in prep., The Amphibians and Reptiles of Arkansas) and NW Louisiana in Caddo Parish (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **EDWARD R. BLACK**, 24 Big Oak Lane, Texarkana, Texas 75503, USA, and **CHRIS T. McALLISTER**, Department of Biology, Texas A&M University at Texarkana, Texarkana, Texas 75505, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). USA: LOUISIANA: VERNON PARISH: Fullerton area, Fort Polk Military Reservation, near jct. Rt. 463 and Jeff McDonald Road (PR 5065). 14 June 2000. Ken Moore, David Plair, and Baeu B. Gregory. Seale Museum of Louisiana, McNeese State University (SML 9324). Verified by Steve Shively. First Parish record; fills the gap between Beauregard and Natchitoches Parishes as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana State University Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA, and **BEAU B. GREGORY**, Environmental and Natural Resources Management Division, Directorate of Public Works, Fort Polk, Louisiana 71459, USA.

OPHEODRYS AESTIVUS (Rough Green Snake). USA: TEXAS: CALLAHAN CO: 28.8 km SE of Abilene. July 1968. Collector not given. Abilene Christian University Natural History Collection (ACUNHC 672). Verified by Mark Muhr. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **ALLAN J. LANDWER**, Department of Biology, Hardin-Simmons University, Abilene, Texas 79698-6165, USA (e-mail: alandwer@hsutx.edu) and **THOMAS E. LEE, JR.**, Department of Biology, Abilene Christian University, Abilene, Texas 79699-7868, USA (e-mail: leet@nicanor.acu.edu).

PITUOPHIS CATENIFER DESERTICOLA (Great Basin Gopher Snake). COLORADO: SAN JUAN CO: W of Silverton, adjacent to South Mineral Creek, T41N, R8W. 28 July 2000. Drayton Harrison and Larry Garcia. UCM Ancillary Collection of Herpetological Slides and Prints 150–151. Verified by Hobart M. Smith. First county record and an elevational record at 9500 ft. (2896 m).

Submitted by **CHARLES W. LOEFFLER**, Colorado Department of Natural Resources, Division of Wildlife, 6060 Broadway, Denver, Colorado 80216, USA.

PSEUDOBOA CORONATA (Crowned False Boa). VENEZUELA: SUCRE: Municipio Benítez: Parcelamiento Guaraúnos (10°35'N, 63°37'W). 2 m. 19 November 2000. Irene Fedón. Museo de Historia Natural La Salle, Caracas (MHNLS 15092, subadult male). Verified by César R. Molina. First state record and northernmost locality in Venezuela. The ocurrence of this snake in the state of Sucre was predicted by Rivas and Oliveros (1997, Herpetofauna del Estado Sucre, Venezuela: Lista Preliminar de Reptiles. Mem. Soc. Cienc. Nat. La Salle 147:67–80). The new record provides a range extension of ca. 50 km NW Caripito, state of Monagas (Roze 1966, La Taxonomía y Zoogeografía de los Ofidios en Venezuela. Ediciones de la Biblioteca, Universidad Central de Venezuela, Caracas. 362 pp.) and nearly 700 km NE Puerto Ayacucho, Amazonas state (Gorzula and Señaris 1999, Contribution to the Herpetofauna of the Venezuelan Guayana I. A Data Base. Scientia Guaianae 8, 270 pp.).

These widely separated localities are noteworthy because they suggest that *P. coronata* belongs to the biogeographical region of Venezuelan Guyana (comprising the states of Amazonas, Bolívar, Delta Amacuro, eastern Monagas, and southeastern Sucre, according to Gorzula and Señaris, *op. cit.*). The pattern of distribution of *Pseudoboa coronata* is repeated (e.g., Gorzula and Señaris, *op. cit.*; Rivas and Oliveros, *op. cit.*) by other reptiles such as *Rhinoclemmys punctularia, Gonatodes humeralis, Hemidactylus palaichthus, Chironius scurrulus, Erythrolamprus aesculapii, Liophis cobella, Micrurus lemniscatus diutius,* and *Pseustes poecilonotus.*

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Sección de Herpetología, Apartado Postal 1930, Caracas 1010-A, Venezuela (e-mail: gilsonrivas@mixmail.com) and **ENRIQUE LA MARCA**, Laboratorio de Biogeografía, Escuela de Geografía, Facultad de Ciencias Forestales y Ambientales, Universidad de Los Andes, Apartado Postal 116, Mérida 5101-A, Venezuela (e-mail: lamarca57@cantv.net).

PSEUDOBOA NEUWIEDII (Neuwied's False Boa). VENEZUELA: ESTADO ANZOATEGUI: Campamento El Caiman del Orinoco, 17 km NE Soledad (8°09'N, 63°32'W, 50 m). 24 October 2000. Paul M. Kornacker. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 73930). Verified by Gilson Rivas Fuenmayor. First state record. The nearest known locality is about 80 km south at Lake Guri (Gorzula and Señaris 1998, Contribution to the herpetofauna of the Venezuelan Guayana I. Scientia Guainae, Caracas. 269 pp.; Kornacker 1999, Checklist and key to the snakes of Venezuela. Lista sistemática y clave para las serpientes de Venezuela. Pako-Verlag, Rheinbach, Germany. 270 pp.; Lancini and Kornacker 1989, Die Schlangen von Venezuela. Verlag Armitano Ed. Caracas. 381 pp.; Roze 1966, La Taxonomía y Zoogeografía de los Ofidios en Venezuela. Univ. Central de Venezuela, Edic. Biblioteca. Caracas. 362 pp.).

Submitted by **PAUL M. KORNACKER**, Aachener Strasse 42, D-53359 Rheinbach, Germany; e-mail: pkornacker@aol.com or pakoverlag@aol.com.

REGINA GRAHAMII (Graham's Crayfish Snake). USA: TEXAS: JONES CO: Fort Phantom Road. 1 April 1960. Collector unknown. Abilene Christian University Natural History Collection (ACUNHC 701). Verified by Mark Muhr. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **ALLAN J. LANDWER**, Department of Biology, Hardin-Simmons University, Abilene, Texas 79698-6165, USA (e-mail: alandwer@hsutx.edu) and **THOMAS E. LEE, JR.**, Department of Biology, Abilene Christian University, Abilene, Texas 79699-7868, USA (e-mail: leet@nicanor.acu.edu).

SALVADORA GRAHAMIAE (Texas Patchnose Snake). USA: TEXAS: TAYLOR CO: 1.6 km N Lake Abilene. 20 November 1999. Thomas E. Lee, Jr. Abilene Christian University Natural History Collection (ACUNHC 248). Verified by Mark Muhr. New county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **ALLAN J. LANDWER**, Department of Biology,

Hardin-Simmons University, Abilene, Texas 79698-6165, USA (e-mail: alandwer@hsutx.edu) and **THOMAS E. LEE, JR.**, Department of Biology, Abilene Christian University, Abilene, Texas 79699-7868, USA (e-mail: leet@nicanor.acu.edu).

SIPHLOPHIS LONGICAUDATUS. BRAZIL: MINAS GERAIS: Município de Mariléia: Parque Estadual do Rio Doce (IEF) (19°42'S, 42°36'W, 536 m). March 1994. R. N. Feio and M. V. Freitas. Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil (MZUFV 812); October 1996. R. N. Feio and M. V. Freitas. MHNCI 7961. Both verified by Júlio César de Moura-Leite. First state record, ca. 400 km west of the closest previous record. Species is restricted to the Atlantic Forest of southern and southeastern Brazil, from Rio Grande do Sul to Espírito Santo States (Peters and Orejas-Miranda 1970, Catalogue of Neotropical Squamata. Part I. Snakes. Smithsonian Inst. Press, Washington, D.C.).

Submitted by **ANA LÚCIA PRUDENTE**, Museu Paraense Emílio Goeldi, Departamento de Zoologia, Seção de Herpetologia, Caixa Postal 399, CEP: 66040-170, Belém, Pará, Brazil, and **RENATO NEVES FEIO**, Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, 36.571-000, Viçosa, Minas Gerais, Brazil.

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: ILLINOIS: Rock Island Co: Lord Thunder Park, Andalusia (Sec. 27, T17N, R3W). 14 August 1957. Gene Forett. HDW-NIU 1788 (formerly RE 088, Putnum Museum of History and Natural Sciences, Davenport, Iowa). Verified by Christine Chandler. New county record; extends range NW of closest records in Hancock County and Peoria County to the east (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28:1–298).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

THAMNOPHIS CYRTOPSIS (Black-necked Gartersnake). USA: ARIZONA: Navajo Co: floodplain of Little Colorado River, ca. 0.8 km ESE Jackrabbit, NW/4 Sec. 15, T18N, R18E, ca. 1506 m elev. 13 June 1999. Trevor B. Persons. UAZ 51740. Red Tank, 22.0 km (by road) S Clear Creek Reservoir bridge on Ariz. Rt. 99. 17 August 1989. Philip C. Rosen. UAZ 49180. Wildcat Canyon at Points of Wildcat. 4 September 1960. R. R. Miller and C. L. Hubbs. UMMZ 121947. 14.9 km (via Ariz. Rt. 77) N Snowflake, then 1.0 km (via dirt road) E. 9 August 1972. C. J. Cole et al. AMNH 109454. Apache Co: 19.6 km (by road) W St. Johns on U.S. Rt. 180. 6 September 1981. Charles H. Lowe and Cecil R. Schwalbe. UAZ 44348. All verified by George L. Bradley, except AMNH 109454 verified by Charles A. Drost. First record for the Little Colorado River, and first records for the Little Colorado River basin other than Lakeside, Navajo County (Milstead 1953, Texas J. Sci. 5:348–379; plotted in Webb 1980, Cat. Am. Amph. Rept. 245.1–245.3; R. G. Webb, pers. comm.), and 2 miles north of Flagstaff, Coconino County, Arizona (MNA Z7.91). The latter location was reported by Aitchison and Tomko (1974, Plateau 47:18–25), but was not plotted by Webb (*op. cit.*; R. G. Webb, pers. comm.). Both previous records are from high elevation sites (>2100 m) straddling the Mogollon Rim. These new records indicate widespread populations in the Little Colorado River basin and suggest a possibility that additional populations might occur in the presently-mapped gap (Rossman et al. 1996, The Garter Snakes. Oklahoma Univ. Press, Norman; Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin Co., Boston, Massachusetts, 350 pp.; Webb, *op. cit.*) between the Mogollon Rim and the San Juan River basin.

Submitted by **TREVOR B. PERSONS**, USGS Forest and Rangeland Ecosystem Science Center, Colorado Plateau Field Station, Box 5614, Northern Arizona University, Flagstaff, Arizona, 86011, USA, and **PHILIP C. ROSEN**, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona 85721, USA.

THAMNOPHIS CYRTOPSIS (Black-necked Gartersnake). USA: TEXAS: Kinney Co: Kickapoo Cavern State Park, 38.8 road km N Brackettville on FM 674. 5 June 2000. John H. Malone. TCWC 83944. Verified by James R. Dixon. County record. (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp). Specimen collected during a baseline amphibian and reptile inventory conducted at Kickapoo Cavern State Park. Collected under the authority of TPWD State Park Scientific Study Permit Number 25-00.

Submitted by **JOHN H. MALONE**, Department of Zoology, University of Oklahoma, 730 Van Vleet Oval, Norman, Oklahoma 73019, USA.

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). USA: OKLAHOMA: Ellis Co: female and 17 of 18 young, 2.5 km N Fargo. 28 June 1975. Richard L. Lardie. Oklahoma Baptist University, Shawnee, Oklahoma (OBU 1364, 1396–1401). New county record; specimens are considered integrades with *T. s. diabolicus* based on ground color. Grant Co: 8.1 km W and 3.2 km S Medford. 20 May 1990. Mark Meier. Saint Gregory's University, Shawnee, Oklahoma (SGU 277); 1.8 km E Hawley. 19 July 1990. Mark Meier. SGU 295; 10 km S and 7.2 km W Manchester. 19 July 1980. R. Lardie. OBU 1819; 2.6 km E Hawley. 11 September 1989. Mark Meier. OBU 2227. SGU specimens previously verified by Jeffrey T. Burkhart. OBU specimens previously verified by the late Jeffrey H. Black. New county records (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, Oklahoma. 370 pp.) and validate sight records for Ellis County (Secor and Carpenter 1984, Oklahoma Herpetol. Soc. Spec. Publ. 1:1–17). Validates Grant County and voucher records (Meier et al. 1990, Bull. Oklahoma Herpetol. Soc. 14[1–4].

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). USA: OKLAHOMA: Major Co: 1.6 km E and 1.7 km S Cleo Springs. 12 June 1989. Lee Frezendall. Saint Gregory's University, Shawnee, Oklahoma (SGU 167); 6.3 km E and 4.8 km S Meno. 19 July 1992. Richard L. Lardie. SGU 329; 6.3 km E and 3.4 km S Meno. 1 July 2000. R. Lardie. SGU 350; 6.3 km E and 6.8 km S Meno. 5 August 1990. R. Lardie. SGU 383; 4.6 km W Isabella. 2 July 1994. R. Lardie. SGU 2000; 3.2 km N and 15.4 km W Fairview. 18 September 1999. R. Lardie. SGU Color Print 13. All verified by Doyle L. Crosswhite. Additional specimens previously collected: 5.1 km E Ames. 27 August 1976. R. Lardie. Okla-

homa Baptist University, Shawnee, Oklahoma (OBU 1468); 12 young born to female collected 1.6 km E and 6.5 km S Cleo Springs (Williams Scout Camp). R. Lardie. OBU 1550; 10.7 km W Orienta. 28 May 1983. R. Lardie. OBU 1605; 3.3 km W and 0.8 km S Ames. 16 June 1985. R. Lardie. OBU 1721; 4.7 km W Ames. 27 September 1975. R. Lardie. OBU 1757. All OBU specimens previously verified by the late Jeffrey H. Black. Specimens are county and verification records (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, Oklahoma. 370 pp.) and validate prior sight records for the county (Secor and Carpenter 1984, Oklahoma Herpetol. Soc. Spec. Publ. 1:1–57). Specimens found west of the Cimarron Gypsum Hills frequently show color characteristics of *T. p. diabolicus* (olive gray to brown ground color) and are considered intergrades between the two subspecies. Those collected from eastern Major County show color characteristics of *T. p. proximus*.

SGU 709; 1.6 km E and 6.5 km S Cleo Springs, Williams Scout Camp. 8 August 1976. OBU 1513 and 16 young (OBU 1514); Williams Scout Camp. 4 August 1976. OBU 1515 and 36 young (OBU 1516); Williams Scout Camp. June 1976. OBU 1517 and 16 young (OBU 1518 & 1519); 9.1 km W Orienta. 28 May 1983. OBU 1605; 3.3 km W and 3.2 km S Ames. 1 July 2000. Specimens were collected by Richard L. Lardie unless otherwise indicated. All SGU specimens were verified by Jeffrey T. Burkhart and Doyle L. Crosswhite. OBU specimens were verified by the late Jeffrey H. Black.

While many of these specimens exhibit color and pattern typical of *T. s. parietalis*, others show characteristics of *T. s. annectens*, as summarized by Collins (1993, Amphibians and Reptiles in Kansas. Third Ed. Univ. Press of Kansas, Lawrence. 397 pp.). These include amount (or lack) of reddish orange between the stripes, color and width of the dorsal stripe (light yellow to bright orange), and uniform dark appearance of the skin, or dark spots arranged in a checkerboard fashion. SGU 2027 with *T. s. annectens* characteristics (no red bars) and SGU 2028, typical *T. s. parietalis*, were collected as they attempted to swallow the same large *Rana blairi*, and there are other examples that verify the two color and pattern variations may be found at the same location. The entire population in northwestern Oklahoma may be intergrades between the two subspecies. Specimens listed above for Ellis, Garfield, Grant, Kingfisher, and Major counties are county records (Webb 1970, Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, Oklahoma. 370 pp.) and validate prior sight records for those counties (Secor and Carpenter 1984, Oklahoma Herpetol. Soc. Spec. Publ. 1:1–17).

The Mariana Islands are a line of 15 small islands in the western Pacific Ocean. The chain extends north from Guam (13°N, 145°E) to Farallon de Pajaraos (= Uracas, 21°N, 146°E). Politically, this portion of the United States is divided into the Territory of Guam (Guam only) and the Commonwealth of the Northern Mariana Islands (all of the others). The larger southern islands—Guam, Rota, Tinian, and Saipan are inhabited, with permanent cities or villages, while most of the far northern islands are uninhabited or have fewer than five families. The islands are oceanic, isolated from continental masses or other large land bodies, and therefore have a rather limited reptile assemblages, with only one endemic species. Interesting variations in the reptile communities among the different islands occur as a product of chance migration and ecological disturbance (natural and human caused), and from the introduction of exotic competitors and predators (Rodda et al. 1991). The most notorious introduced predator is the brown treesnake, *Boiga irregularis*, which colonized Guam shortly after World War II (Rodda et al. 1991, 1999), but the herpetofauna has been greatly influenced by a variety of other introduced species as well, both historically (Fritts and Rodda 1998) and prehistorically (Pregill 1998). The inhabited southern islands are at greatest risk from the brown treesnake and other introductions, several of which have occurred since the last Mariana checklist (Rodda et al. 1991), and are here documented. In addition, recent excursions to the uninhabited far northern islands have produced new island records.

With one exception, voucher specimens were collected and verified by and deposited in the U.S. National Museum (USNM, Smithsonian Institution; hyphenated catalog numbers represent ranges). The exception is a sight record on Farallon de Medinilla of *Emoia caeruleocauda*, which could not be collected because of unexploded cluster bombs in the vicinity (the military escort to this target island was unyielding, and an approaching typhoon terminated all visitation within hours of the sighting). Island names are those given on U.S. Geological Survey maps; where local usage varies, the more widely used name is given parenthetically. We report a total of fifteen new records on seven different islands.

Anolis carolinensis. Tinian Island; immediate vicinity of the Commercial Port. 22 May 1997, Gad Perry. USNM 532060. This record suggests a recent introduction on the basis of its location and because this species was not detected in the area in 1985 by Wiles et al. (1989) and during targeted searches in 1989 by GHR and others. That the species should colonize Tinian is not surprising in light of its presence on all of the other inhabited southern Mariana Islands (Rodda et al. 1991). Tinian has the most disturbed habitats among these islands, and this species thrives in comparable snake-free disturbed habitat on Rota and Saipan.

Carlia fusca. Rota Island; in the immediate vicinity of the Commercial Port. 2 October 1997. Stanley J. Kot. USNM 532102–10. This record suggests a recent introduction, on the basis of its location and because this species was not detected in the area by Wiles et al. (1990) and during targeted searches in 1994 and 1995 by EWC. This species occurs in high densities on the other inhabited southern islands (all established during the 1950s and 1960s: Wiles and Guerrero 1996; Rodda et al. 1991). This, coupled with daily cargo movement between the islands, greatly facilitated an introduction to Rota. Rota has the least disturbed habitats among these islands, and native forests on Rota may limit or slow the spread of this heliophilic skink. This species, exotic to the Mariana Islands, may have a detrimental effect on native skink species (Rodda et al. 1991) and deserves close monitoring.

Cryptoblepharus poecilopleurus. Farallon de Medinilla. 5 November 1996. John Goody. USNM 521932. Rota Island; at overlook above Bird Sanctuary (elevation ca 90m). 3 October 1997. Stanley J. Kot. USNM 532111–15. Saipan, 20 September 1999. North-central end of the island in the Marpi Commonwealth Forest. Scott R. Vogt. USNM 529970. Neither the Rota record (e.g., Wiles et. al. 1990) nor the Saipan record (e.g., Wiles and Guerrero 1996) are new but both are first time records, on each island, for this species away from the vicinity of salt water.

Emoia atrocostata. Aguijan Island (= Aguigan, Goat Island); W end of island in rocky strand and grassy habitat. 24 March 1995. Earl W. Campbell. USNM 348676–9.

Emoia caeruleocauda. Farallon de Medinilla. 5 November 1996. Scott R. Vogt sight record, not vouchered as explained above. Identification was based on the absence of any other species of blue-tailed striped skinks in the region.

Emoia slevini. Sarigan Island (Sariguan Island). June 1996, 13 March 1997, 6 January 1998. Scott R. Vogt. USNM 521970–8. Ground level vegetation was severely degraded by goat overgrazing during the earlier visits; vegetative recovery, after a feral ungulate removal program, was evident during later collections. Based on sticky trap capture rates, population numbers of this species on Sarigan appear to be increasing after the feral ungulate removal program. Pagan Island. 24–31 August 1999. Scott R. Vogt USNM 529972. Documented on the south end of the island with glueboard surveys. The northern region of Pagan was the site of a volcanic eruption in 1981, and this area still has low lizard densities (even in areas with similar vegetation) as compared to the southern end. This species was the subject of extensive (3451 trap hours on Aguijan and 300 on Anatahan) but unsuccessful targeted glueboard surveys and visual searches on Aguijan in March 1995 and on Anatahan in November 1995.

Gehyra mutilata. Aguijan Island (Goat Island). 24–25 March 1995. Earl W. Campbell. USNM 348637–40.

Gehyra oceanica. Anatahan Island; old village area near the NW corner of the island. November 1995. Scott R. Vogt. USNM 534531. Sarigan Island (Sariguan Island); old village area on the NW corner of the island. 13 March 1997. Scott R. Vogt. USNM 521927.

Hemidactylus frenatus. Aguijan Island (Goat Island), in introduced forest. 23 March 1995. Earl W. Campbell. USNM 348652–7.

Lepidodactylus lugubris. Sarigan Island (Sariguan Island); old village area on the Northwest corner of the island in coconut forest habitat. 12 March 1997. Scott R. Vogt. USNM 521930.

Nactus pelagicus. Sarigan Island (Sariguan Island); central area of the island (upper elevations) in native forest stand. 13 March 1997. Scott R. Vogt. USNM 5219298–9.

Perochirus ateles. Rota Island; North-central part of island near the public landfill. June 1998. Robert N. Reed. USNM 521320. This once common Micronesian endemic (Pregill 1998) is no longer present in substantial numbers. Our specimen is the first historical record for Rota. That it was undetected in extensive prior surveys (Wiles et al. 1990, and numerous subsequent collecting trips by each of the authors) indicates that it has become exceptionally rare.

New Records of Squamate Reptiles in the Central Brazilian Cerrado: Emas National Park Region

PAULA HANNA VALDUJO
Laboratorio de Herpetologia, Instituto Butantan
Avenida Vital Brazil, 1500. CEP 05503-900
São Paulo, São Paulo, Brazil

and

CRISTIANO NOGUEIRA
Departamento de Ecologia General, Universidade de São Paulo
R. do Matão, 321, trav. 14. CEP 05508-900
São Paulo, São Paulo, Brazil

The Cerrado represents the second largest neotropical ecosystem, ocuppying 2,000,000 km^2 in central Brazil (Eiten 1972). However, it remains one of the least explored neotropical regions in terms of zoological studies (Colli et al. 1998). Species lists providing voucher specimens for central Brazilian squamate reptiles are available only in Amaral (1935) and Hoge (1952a, b).

Here we provide a list of sixteen species of lizards, amphisbenians, and snakes from Emas National Park region (ENP, 18°20'S, 53°00'W, 760–880 m elev., ca.130,000 ha), that represent range extensions or first reports for the Brazilian Cerrado. Sampling efforts included an area of 31,400 km^2, covering all the area inside ENP and immediate vicinities, in the states of Goiás, Mato Grosso do Sul, and Mato Grosso.

This work presents part of the results obtained in an ongoing long-term study on the squamate reptiles in the Emas National Park region, having sampled over 70 squamate reptile taxa up to May 2001. The collected specimens cited herein are deposited in the herpetological collections of Instituto Butantan (IB, verified by G. Puorto and F. L. Franco), Museu de Zoologia da Universidade de São Paulo (MZUSP, verified by P. E. Vanzolini), Universidade

de Brasília (CHUNB, verified by G. R. Colli) and Universidade Estadual de Campinas (ZUEC, verified by P. Manzani).

Lacertilia

Bachia cacerensis. Emas National Park, Agua Ruim river region, Jacuba drainage, 15 km from main lodge. 18°08.41'S, 52°44.49'W. 14 February 1999. F. Rodrigues, C. Nogueira, and P. H. Valdujo. CHUNB 11577. First record for state of Goiás. Extends range ca. 450 km SE from nearest record in Cáceres, MT (Castrillon and Strüssmann 1998).

Amphisbaenia

Amphisbaena silvestrii. Emas National Park, close to Jacuba base. M. B. Ramos-Neto. MZUSP 87733. Extends range ca. 250 km S of nearest recorded locality, Aruanã, GO (Vanzolini 1997).

Serpentes

Apostolepis assimilis. Emas National Park, next to Jacuba base. 19 April 1997. M. B. Ramos-Neto. IB 62649. First record in a 300 km radius. Nearest recorded locality is Ilha Solteira, SP (Hoge et al. 1975).

Helicops gomesi. Emas National Park, close to Formoso River bridge. 18°15.65'S, 52°53.32'W. April 1997. M. B. Ramos-Neto. IB 62688. According to Rossman (1970), this species is known from localities along the Tietê River (Paraná drainage) in the state of São Paulo. First record for the state of Goiás.

Leptodeira annulata pulchriceps. Goiás, Chapadão do Céu municipality. 4 May 1997. A. P. Peña. IB 57135. First record for Goiás state, extends range 400 km NE of nearest recorded locality, Aquidauana, in the state of Mato Grosso do Sul (Duellman 1958).

Leptotyphlops koppesi. Emas National Park, P2 point, 20 km N of main lodge. 18°06.53'S, 52°55.20'W. 10 September 1998. N. Hulle, C. Nogueira, and P. H. Valdujo. IB 58708. First state record, extending range ca. 350 km E of single known record in Terenos, state of Mato Grosso do Sul, type locality for the species (McDiarmid et al. 1999).

Liophis frenatus. Goiás, Chapadão do Céu municipality. A. P. Peña. IB 62704. First state record, extending range about 300 km N of nearest recorded locality, Ilha Solteira, state of São Paulo (Hoge et al. 1975).

Liophis maryellenae. Emas National Park, wet grassland in Agua Ruim river region, Jacuba drainage, 15 km from main lodge. 18°08.41'S, 52°44.49'W. April 2000. C. Nogueira. IB 62691. Extends range about 500 km W of nearest recorded locality, Anápolis, state of Goiás (type locality, Dixon 1985).

Liophis meridionalis. Emas National Park, Gloria River region, 10 km from main lodge. 18°17.10'S, 53°00.51'W. 18 February 1999. R. Brandão and C. Nogueira. IB 62681. First record in a 350 km radius. Nearest recorded locality: Terenos, state of Mato Grosso do Sul (Hoge 1952c).

Liophis paucidens. Goiás, Mineiros municipality, assentamento Babilônia. 17°40.90'S, 53°13.20'W. 21 July 2000. P. H. Valdujo. IB 62696. Few known specimens, all from northeastern or central Brazil. Extends range about 550 km W of nearest recorded locality, Ipameri, state of Goiás (Michaud and Dixon 1987).

Liophis reginae macrosoma. Goiás, Chapadão do Céu municipality, Santa Amélia Farm. 23 February 1998. A. P. Peña. IB 62683. New distribution record in a 300 km radius. Nearest recorded locality is Ilha Solteira, state of São Paulo (Dixon 1983; Hoge et al. 1975).

Oxyrhopus petola digitalis. Emas National Park, close to J point, 3 km E from main lodge. 17°35.46'S, 52°38.61'. W. F. Rodrigues. ZUEC 01914. First state record (Bailey 1970).

Oxyrhopus rhombifer rhombifer. Emas National Park, close to B point, 3 km S of main lodge. 18°18.39'S, 52°53.93'. W. F. Rodrigues. ZUEC 1914. First record for state of Goiás (Bailey 1970).

Phalotris nasutus. Emas National Park, close to P2 point, 20 km N of main lodge. 18°06.53'S, 52°55.20'W. November 1994. F. Rodrigues. CHUNB 03892. Extends range ca. 100 km E from nearest recorded locality, Baliza, state of Goiás (Ferrarezzi 1993).

Philodryas patagoniensis. Emas National Park, next to V point, 25 km N of main base. 18°03.33'S 52°56.12'W. 14 October 1999. L. Baumgarten. CHUNB 18440. First precise locality for state of Goiás. Northernmost record for Brazil (Thomas 1976).

Taeniophallus occipitalis. Emas National Park, close to Formoso River bridge. 18°15.65'S, 52°53.32'W. 19 July 1999. P. H. Valdujo. IB 62692. First record for state of Goiás, according to Myers (1974), whose list of examined specimens does not show any precise locality in the country.

Acknowledgments.—We thank A. Eterovic, A. P. Peña, F. Rodrigues, L. Baumgarten, M. Martins, M. B. Ramos-Neto, N. Hülle, O. Marques, and R. Brandão for helping during fieldwork; C. C. Mello and P. E. Vanzolini for the identification of *A. silvestrii*; and A. S. dos Santos and IBAMA (permit no. 02001.002355/96-29) for allowing us to work and collect at Emas National Park. The CNPq (Brazilian Research Council) and FAPESP provided fellowships to the authors. This work is part of the project *Vertebrates from Emas National Park,* financially supported by Fundação O Boticário de Proteção à Natureza/McArthur Foundation, The BP Conservation Programme, Fauna Flora International, and BirdLife International.

New Records for Amphibians and Reptiles from Departamentos Pasco and Ucayali, Peru

EDGAR LEHR

Forschungsinstitut und Naturmuseum Senckenberg
Senckenberganlage 25, D-60325 Frankfurt am Main, Germany
e-mail: edgarlehr@hotmail.com

The composition of the herpetofauna of the Peruvian Departamentos Pasco and Ucayali is still poorly known. Distribution data for amphibians and reptiles from Pasco (Lehr 2000a; Lehr and Fernandez 2000a), and Ucayali (Duellman and Thomas 1996; Lehr 2000b, Lehr and Aguilar 2000a, b; Lehr and Fernandez 2000b; Lehr and Köhler 2000) were published recently. Here I document 34 new records for amphibians and reptiles from Departamento Pasco, and nine new records for amphibians and reptiles from Departamento Ucayali based on the species lists of Rodríguez et al. (1993), Carrillo de Espinoza and Icochea (1995), and Duellman and Thomas (1996).

All specimens were deposited at Museo de Historia Natural de San Marcos (MHNSM), and Natur-Museum und Forschungsinstitut Senckenberg (SMF). Snakes from the collection of the Centro de Salud San Camilo Pozuzo (PE) were included for Pasco records.

All amphibians were verified by J. Icochea except *Osteocephalus planiceps*, which was verified by K.-H. Jungfer; caiman, tortoises, and lizards were verified by G. Köhler, and snakes were verified by N. Carrillo de Espinoza.

Anura

Eleutherodactylus diadematus (Diadem Robber Frog). UCAYALI: Provincia Atalaya: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 19 June 1998. E. Lehr. MHNSM 20374.

Leptodactylus knudseni (Knudsen's Frog). UCAYALI: Provincia Atalaya: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 2 February 1999. E. Lehr and C. Aguilar. MHNSM 20398.

Leptodactylus rhodonotus (Peru White-lipped Frog). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 25 July 1998. E. Lehr and R. Fernandez. MHNSM 20410–11, SMF 80435–36.

Lithodytes lineatus (Gold-striped Frog). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 20 May1999. E. Lehr. SMF 80438; Puerto Amistad (09°55'41"S, 74°55'25"W, 200 m elev.). 25 May 1999. E. Lehr. MHNSM 20412.

Hemiphractus scutatus (Spix's Horned Treefrog). UCAYALI: Provincia Atalaya: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 31 January 1999. E. Lehr. SMF 80437.

Hyla boans (Rusty Treefrog). PASCO: Provincia Oxapampa: Puerto Amistad (09°55'41"S, 74°55'25"W, 200 m elev.). 25 May 1999. E. Lehr. MHNSM 20336–37, SMF 80349–51.

Hyla calcarata (Troschel's Treefrog). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 18 May 1999. C. Aguilar. SMF 80352.

Hyla geographica (Map Treefrog). PASCO: Provincia Oxapampa: Puerto Amistad (09°55'41"S, 74°55'25"W, 200 m elev.). 25 May 1999. E. Lehr. MHNSM 20339–40, SMF 80355.

Hyla phyllognatha (Roque Treefrog). PASCO: Provincia Oxapampa: Pozuzo (10°04'10"S, 75°31'42"W, 1000 m elev.). 11 July 1998. E. Lehr. MHNSM 20343–44, SMF 80359; Iscozacin/ Cordillera San Matías (10°10'41"S, 75°07'54"W, 410 m elev.). 13 May 1999. E. Lehr and E. Ponce. SMF 80362.

Hyla punctata (Polkadot Treefrog). PASCO: Provincia Oxapampa: Iscozacin/Cordillera San Matías (10°10'41"S, 75°07'54"W, 410 m elev.). 16 May 1999. E. Lehr and E. Ponce. MHNSM 20347.

Osteocephalus planiceps (Slender-legged Treefrog). PASCO: Provincia Oxapampa: Pozuzo (10°04'10"S, 75°31'42"W, 1000 m elev.). 24 February 1999. E. Lehr. SMF 80365; UCAYALI: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 19.06.1998. E. Lehr and R. Fernandez. SMF 80367.

Phyllomedusa vaillanti (White-lined Leaf Frog). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 18 May 1999. E. Lehr and E. Ponce. MHNSM 20355, SMF 80373.

Gymnophiona

Siphonops annulatus (Ringed Caecilian). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 25 July 1998. E. Lehr. SMF 80486.

Testudines

Geochelone denticulata (South American Yellowfoot Tortoise). PASCO: Provincia Oxapampa: Puerto Amistad: (09°55'41"S, 74°55'25"W, 200 m elev.). 24 May 1999. Obtained from locals.

SMF 80080–81.

Lacertilia

Hemidactylus mabouia (Cosmopolitan House Gecko). PASCO: Provincia Oxapampa: Ciudad Constitución (09°50'56"S, 75°00'56"W, 200 m elev.). 24 May 1999. E. Lehr and E. Ponce. SMF 80088.

Anolis fuscoauratus (Brown-eared Anole). PASCO: Provincia Oxapampa: Pozuzo (10°04'10"S, 75°31'42"W, 940 m elev.). 11 July 1998. E. Lehr. MHNSM 20136; Pozuzo (10°04'10"S, 75°31'42"W, 780 m elev.). 26 February 1999. C. Aguilar. MHNSM 20137.

Polychrus marmoratus (Many-colored Bush Anole). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 20 May 1999. Obtained from a local resident. MHNSM 20139.

Alopoglossus angulatus (Northern Teiid). UCAYALI: Provincia Atalaya: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 25 January 1999. E. Lehr. SMF 80100.

Prionodactylus argulus (White-lipped Prionodactylus). PASCO: Provincia Oxapampa: Pozuzo (10°10'23"S, 75°35'13"W, 922 m elev.). 8 March 1999. E. Lehr. MHNSM 20087.

Ptychoglossus brevifrontalis (Boulenger's Largescale Lizard). UCAYALI: Provincia Atalaya: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 12 June 1998. E. Lehr. MHNSM 20088.

Cercosaura ocellata (Ocellated Tegu). PASCO: Provincia Oxapampa: Iscozacin/Cordillera San Matías (10°10'41"S, 75°07'54"W, 580 m elev.). 15. May 1999. E. Ponce. SMF 80103; UCAYALI: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 23 June 1998. E. Lehr. SMF 80102.

Mabuya bistriata (Two-striped Mabuya). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 10 March 1999. E. Lehr. SMF 80133.

Tropidurus umbra (Lava Lizard). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 20 May 1999. Obtained from a local resident. SMF 80237; UCAYALI: Provincia Atalaya: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 11 June 1998. E. Lehr. MHNSM 20231.

Serpentes

Boa constrictor (Boa Constrictor). PASCO: Provincia Oxapampa: Iscozacin (ca. 320 m elev.). 20 May 1999. Obtained from a local resident, who claimed to have caught it south of Iscozacin. SMF 80016.

Corallus caninus (Emerald Tree Boa). PASCO: Provincia Oxapampa: Pozuzo (10°10'23"S, 75°35'13"W, 1000 m elev.). 9 July 1999. D. Schuler. MHNSM 20003, SMF 80017.

Chironius fuscus (Brown Sipo). PASCO: Provincia Oxapampa: Pozuzo (10°10'23"S, 75°35'13"W, 900 m elev.). 9 March 1999. E. Lehr. SMF 80026.

Clelia clelia (Mussurana). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 6 March 1999. E. Lehr. SMF 80027.

Dipsas catesbyi (Catesby's Snaileater). PASCO: Provincia Oxapampa: Pozuzo (10°04'10"S, 75°31'42"W, 940 m elev.). 12 July 1998. E. Lehr. SMF 80028.

Leptodeira annulata (Banded Cat-eyed Snake). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 20 May 1999. SMF 80035.

Liophis reginae (Royal Ground Snake). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 9 July 1999. E. Lehr. SMF 80037.

Oxyrhopus petola (Calico False Coral Snake). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 21 March 1996. J. Lara. PE 1152.

Pseustes sulphureus (Amazon Puffing Snake). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 25 February 1995. J. Lara. PE 1185. 13 May 1995. C. Köhel. PE 1189.

Tantilla melanocephala (Black-headed Snake). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 10 March 1999. Obtained from a local resident. SMF 80060; 9 July 1999. Obtained from a local resident. SMF 80061.

Xenodon rabdocephalus (False Fer-de-lance). PASCO: Provincia Oxapampa: Pozuzo (10°07'01"S, 75°32'11"W, 770 m elev.). 9 July. A. Egg. MHNSM 20007; UCAYALI: Bolognesi (10°06'13"S, 73°49'02"W, 230 m elev.). 26 January 1999. E. Lehr and C. Aguilar. SMF 80063; 31 January 1999. E. Lehr. MHNSM 20066.

Xenodon severus (Amazon False Fer-de-lance). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 21 May 1999. E. Lehr and E. Ponce. SMF 80079.

Xenopholis scalaris (Wucherer's Ground Snake). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 18 May 1999. E. Lehr. SMF 80065.

Micrurus spixii (Amazon Coral Snake): PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 20 May 1999. Obtained from a local. SMF 80069.

Bothriopsis bilineata (Two-striped Forest Pit Viper). PASCO: Provincia Oxapampa: Iscozacin (10°12'05"S, 75°09'23"W, 320 m elev.). 21 May 1999. E. Lehr. SMF 80070.

Crocodylia

Caiman crocodilus (Narrowsnout Spectacled Caiman). PASCO: Provincia Oxapampa: Iscozacin/Río Palcazu (10°12'05"S, 75°09'23"W, 320 m elev.). 21 May 1999. Obtained from a local. MHNSM 20020.

Achnowledgments.—I thank N. Carrillo de Espinoza, J. Icochea, K.-H. Jungfer, and G. Köhler for their help in identification of the species, and C. Aguilar, R. Fernandez and E. Ponce for their assitance in field work. Collecting permits were provided by the Ministerio de Agricultura (INRENA), Lima, Peru. Research was supported with a grant from the German Academic Exchange Service (DAAD), Bonn.

New Amphibian and Reptile Records in Northwestern Illinois

ALLAN L. MARKEZICH
and
DARRYL J. BECKETT
Department of Natural Sciences & Engineering, Black Hawk College
6600 34th Avenue, Moline, Illinois 61265, USA
e-mail (ALM): markezicha@bhc1.bhc.edu

From the time of Phil Smith's comprehensive work (1961) until the early 1990s, there has been little modification of our understanding of the geographic distribution of much of the Illinois herpetofauna. Recently, increased work in the field and examination of collections has led to a better understanding on both regional (Tucker 1994; Wilson, 1999) and statewide (Redmer and Ballard 1995; Petzing et al. 1998, 2000) levels. Still, the distribution of the herpetofauna in several areas of the state, including relatively populated ones, has largely remained unrevised and unstudied presumably due to the historical absence of workers or organized field work. The northwestern Illinois region involving Rock Island County and adjacent or nearby counties to the south is an example of such an understudied area. Past collection efforts there have been infrequent and sporadic; consequently, many relatively common species in this region are currently undocumented (Phillips et al. 1999), and many of the most recent voucher specimens were collected in the 1940s and 1950s.

In an effort to update our knowledge of distributions in this region of Illinois, we made comprehensive collections of amphibians and reptiles in several counties during the past several years. We relied on Phillips et al. (1999) and specific locality data from museum collections to verify the current knowledge of geographical distributions of species and the recency of previous collections. In this paper we present 14 new county records (abbreviated "NCR" in the text) and 19 updated county records ("UCR") if the species had not been documented for at least twenty years from a particular county, a standard adopted by Phillips et al. (1999). Many of the UCR's we report actually update records that are 40–60 years old. In several cases we report significant range extensions within particular counties, particularly if the species is known from only one previously documented record and the present specimen is in a different and distant locality within the county. Christopher A. Phillips verified identifications of all specimens, and they are housed in the herpetological collections of the Illinois Natural History Survey (INHS). Several anuran specimens reported upon here are also represented by tissue samples in the INHS Herpetological Tissue Collection.

Anura

Bufo americanus (American Toad). HENRY CO: on road 1400N, 0.6 km E of Osco Rd. 16 April 2000. A. L. Markezich. INHS 16780. UCR. DOR adult collected at 2050 h; MERCER CO: jct. Edwards River and U. S. Rt. 67, NE corner. 24 March 2000. A. L. Markezich and D. J. Beckett. INHS 16778. NCR. Adult collected at 2045–2200 h.

Bufo fowleri (Fowler's Toad). HENDERSON CO: Bald Bluff Rd. (Co. Rd. 2650N), 1.6 km E of Keithsburg Blacktop (Co. Rd. 1350E). 16 September 1995. A. L. Markezich. INHS 16781. UCR. DOR adult collected at 1930 h.

Acris crepitans (Northern Cricket Frog). HENRY CO: Izaak Walton Giant Goose Conservation Area, 3.2 km ESE Atkinson. E end Stiner Lake, 14 October 2000, 1600 h. D. J. Beckett. INHS 16764. Adult collected at 1600 h and included because locality is 30 linear km east of county record reported by Petzing et al. (1998).

Hyla chrysoscelis/versicolor (Gray Treefrog complex). MERCER CO: 5 km ENE Viola. 12 May 2000. D.J. Beckett. INHS 16767. NCR. Adult collected at 1900 h.

Pseudacris triseriata (Western Chorus Frog). HENDERSON CO: 5 km N Biggsville, small pond SE jct. Co. Rd. 1850S and Co. Rd. 1675E. 24 March 2000. A. L. Markezich. INHS 16768. NCR. Adult collected at 1530 h; HENRY CO: Izaak Walton Giant Goose Conservation Area, 3.2 km ESE Atkinson. 30 March 2000, A. L. and M. L. Markezich. INHS 16776. NCR. Adult collected at 2040 h; MERCER CO: jct. Edwards River and U.S. Rt. 67, NE corner. 24 March 2000, A. L. Markezich and D. J. Beckett. INHS 16773. NCR. Adult collected at 2045–2200 h; 50 m N of Keithsburg levee, N edge of town. 24 March 2000. A. L. Markezich and D. J. Beckett. INHS 16769. Adult collected at 1845–1925 h and included because locality is in the extreme southwestern portion of county, 35 linear km WSW of the new county record.

Rana blairi (Plains Leopard Frog). HENDERSON CO: Bald Bluff Rd. (Co. Rd. 2650N), 1.9 km E Big River State Forest. 16 September 1995, 2000 h. A. L. Markezich. INHS 16791. DOR adult, included because locality is 33 km north of county record reported by Petzing et al. (1998); HENRY CO: Izaak Walton Giant Goose Conservation Area, 3.2 km ESE Atkinson. E end of Stiner Lake. 18 October 2000. A. L. Markezich. INHS 16795. NCR. Adult collected at 1540–1600 h; MERCER CO: eastern edge of Keithsburg, unimproved road in Pope Creek bottoms. 31 March 2000. A. L. Markezich and D. J. Beckett. INHS 16792. Adult collected at 2105 h and included because locality is in extreme southwestern portion of the county, 31 linear km west of the previous record (Petzing et al. 2000);

ROCK ISLAND CO: 9 km W Andalusia, Loud Thunder recreational area, 40 m from Mississippi River along creek below Lake George. 28 September 2000. A. L. Markezich and D. J. Beckett. INHS 16793. NCR. Adult collected at 1630 h.

Rana catesbeiana (Bullfrog). HENRY CO: SE Atkinson on Co. Rd.1700N, 1.1 km E of Co. Rd. 2350E. 16 April 2000. A. L. Markezich. INHS 16797. NCR. Adult collected at 2015 h; MERCER CO: 50 m N of Keithsburg levee, N edge of town. 24 March 2000, 1845–1925 h. A. L. Markezich and D. J. Beckett. INHS 16796. Adult, included because locality is in extreme southwestern portion of county, 32 linear km west of the previous record (Petzing et al., 2000); ROCK ISLAND CO: 9 km W Andalusia, Loud Thunder Cub Scout Camp. 2 October 2000. A. L. Markezich. INHS 16799. NCR. Juvenile collected at 1715 h; South Moline Twp., ditch bordering Poplar Grove Rd., 1.6 km S of Ill. Rt. 5. 12 October 2000. A. L. Markezich and D. J. Beckett. INHS 16801. Juvenile collected at 1430–1600 h and included because locality is 30 linear km east of new county record.

Rana clamitans (Green Frog). HENRY CO: Izaak Walton Giant Goose Conservation Area, 3.2 km ESE Atkinson. Small pond across road from Stiner Lake. 18 October 2000. A. L. Markezich. INHS 16805. NCR. Adult collected at 1640 h; ROCK ISLAND CO: 9 km W Andalusia, Loud Thunder Cub Scout Camp. 2 October 2000. A. L. Markezich. INHS 16804. UCR. Adult collected at 1745 h.

Rana pipiens (Northern Leopard Frog). HENRY CO: Izaak Walton Giant Goose Conservation Area, 3.2 km ESE Atkinson. 18 October 2000, A. L. Markezich. INHS 16789. UCR. Adult collected at 1540–1600 h; MERCER CO: jct. Edwards River and U.S. Rt. 67, NE corner. 24 March 2000. A. L. Markezich and D. J. Beckett. INHS 16783. NCR. Juvenile collected at 2045–2200 h; ROCK ISLAND CO: 9 km W Andalusia, Loud Thunder Cub Scout Camp. 29 September 2000. A. L. and M. L. Markezich. INHS 16786. UCR. Adult collected at 1630 h; South Moline Twp., ditch bordering Poplar Grove Rd., 1.6 km S of Ill. Rt. 5. 12 October 2000. A. L. Markezich and D. J. Beckett. INHS 16787. Adult collected at 1430–1600 h and included because locality is 30 linear km east of updated county record.

Testudines

Chrysemys picta (Painted Turtle). HENDERSON CO: Big River State Forest Campground. 30 May 1996. A. L. Markezich and A. Weeks. INHS 15687. UCR. Fresh shell, adult.

Serpentes

Coluber constrictor (Racer). HENDERSON CO: 0.8 km E Oquawka on Keithsburg Blacktop, (Co. Rd. 1350E),1.4 km N of Illinois Rt. 164. 15 September 1995. A. L. Markezich. INHS 16808. UCR. DOR adult; HENRY CO: 5.6 km N Orion on Co. Rd. 450 E. 15 May 1992, 1630 h. A. L. Markezich. INHS 16809. UCR. DOR adult. MERCER CO: 2.4 km S Aledo on Ill. Rt. 94. 1 October 1995. A. L. Markezich. INHS 16810. UCR. DOR adult collected at 0930 h.

Elaphe vulpina (Western Fox Snake). HENDERSON CO: Illinois Rt. 94, 0.5 km N jct. Ill. Rt. 164. 26 September 1997. A. L. Markezich. INHS 16813. UCR. DOR juvenile collected at 1345 h; HENRY CO: 4 km N Orion on Co. Rd. 350E. 26 September 1996. A. L. Markezich. INHS 16814. UCR. DOR adult collected at 2015 h; ROCK ISLAND CO: 1.5 km W of U.S. Rt. 67 on 176th Avenue. 29 September 1995. A. L. Markezich. INHS 16816. UCR. DOR adult collected at 1930 h.

Heterodon platirhinos (Eastern Hognose Snake). HENDERSON CO: Keithsburg Blacktop Rd. at entrance to Delabar State Park. 31 May 1996, 1530 h. A. L. Markezich. INHS 15693. UCR. DOR, large adult.

Lampropeltis calligaster (Prairie Kingsnake). HENDERSON CO: SW edge of Gladstone on road to Henderson County Conservation Area. 15 September 1995. A. L. Markezich. INHS 15694. NCR. DOR adult collected at 1300 h; Keithsburg Blacktop (Co. Rd. 1350E) at Hoskins Bend, 5.1 km S Big River State Forest headquarters. 9 July 1996. A. L. Markezich and J. Horger. INHS 15696. DOR adult collected at 1215 h and included because locality is 23 km north of county record, representing the northernmost occurrence of this species in western Illinois.

Lampropeltis triangulum (Milk Snake). ROCK ISLAND CO: W of Andalusia, near Lake George. 13 September 1992. Ken Pratt. INHS 16817. UCR. Juvenile killed in backyard of home in a forested area.

Nerodia sipedon (Northern Water Snake). MERCER CO: 11 km N Rt. 17 on Muscatine-New Boston Rd. 20 September 1996. A. L. Markezich. INHS 15692. NCR. DOR adult collected at 1600 h.

Pituophis melanoleucus (Bullsnake). HENDERSON CO: E edge of Big River State Forest on Co. Rd. 1500E, 1.9 km N of Co. Rd. 2450N. 29 September 1995. A. L. Markezich. INHS 15684. NCR. DOR adult collected at 0900 h.

Storeria dekayi (Brown Snake). HENRY CO: 3.2 km ESE Atkinson on Co. Rd. 2350E. 16 April 2000. A. L. Markezich. INHS 16818. UCR. DOR adult collected at 1950 h; ROCK ISLAND CO: 176th Avenue, 1.4 km E of Co. Rd. 3000E. 13 October 1995. A. L. Markezich. INHS 15688. UCR. DOR adult collected at 1030 h.

Thamnophis radix (Plains Garter Snake). HENRY CO: 1.6 km N Orion on Co. Rd. 350E. 4 May 1999. A. L. Markezich. INHS 16819. UCR. DOR adult collected at 1600 h.

Thamnophis sirtalis (Eastern Garter Snake). HANCOCK CO: Ill. Rt. 9, 3.2 km W Dallas City. 26 September 1997. A. L. Markezich. INHS 16822. UCR. DOR adult collected at 1430 h; MERCER CO: Rt. 94 near Edwards River, 3.2 km N Ill. Rt. 17 in Aledo. 13 October 1995. A. L. Markezich. INHS 15690. UCR. DOR adult collected at 1100 h.

Acknowledgments.—We are grateful to John E. Petzing and Christopher A. Phillips of the Illinois Natural History Survey for furnishing various data to us, verifying specimen identifications, and critically reading the manuscript. We appreciate both the help and permission granted by Ted Larimer of the Izaak Walton League and Arlin Neumann of the Loud Thunder Scout Camp. ALM would especially like to thank the Horger family and Matthew L. and Madelynn J. Markezich for various types of assistance and support during the project. Finally, we wish to thank the Illinois Wildlife Preservation Fund of the Illinois Department of Natural Resources for grants 96-003 and 98-015 to ALM; these funds in part supported field work in Henderson County.

The Islas de la Bahía form a small archipelago off the northcentral coast of Honduras. This archipelago consists of three major islands (Utila, Roatán, Guanaja), three smaller islands at the eastern end of Isla Roatán (Santa Elena, Morat, Barbareta), and numerous small, uninhabited cays. The herpetofaunal composition of the Islas de la Bahía was first outlined by Wilson and Hahn (1973) in an effort to present new distributional records and to clarify the taxonomy of reptiles and amphibians from primarily the three major islands. Since that time there have been only a few additions to the herpetofauna of the Bay Islands (de Queiroz 1987; Köhler 1996a, b, 1998a, b; McCranie and Köhler 1999; Villa and McCranie 1995). The herpetofauna of the smaller islands has never been addressed in any detail and we here report the results of a brief survey of Islas Barbareta, Morat, and Big Pigeon Cay, taken on 13 July 2000 as part of the Tropical Field Biology summer course taught on Isla Roatán through La Sierra University. Specimens were photographed (LSUPC = La Sierra University Photographic Collection), tissued, and catalogued in the herpetological collection of La Sierra University (LSUHC). Specimen identifications were verified by Roland Sosa (Department of Natural Sciences, Loma Linda University).

Isla Barbareta

Isla Barbareta (area ca. 506 ha; Fig. 1) is approximately 6 km long and 2 km wide and privately owned. It is the largest of the three smaller Bay Islands, and lies only 4 km off the western end of Isla Roatán. Barbareta's only developments are a small resort on the western end and an abandoned airstrip at the southern tip; overall, it has suffered very little in the way of human disturbances. As a result, it is covered in lush primary forest. Previous records of reptiles from Barbareta are limited to the species list in Wilson and Hahn (1973). Their list was based on material collected in 1947 and 1948 by Arthur C. Twomey and included only *Anolis allisoni* and *Oxybelis aeneus*. Since publication of that list, two taxonomic reassignments are of interest to our listing below. Specimens of *Sphaerodactylus continentalis* were reidentified as *S. millepunctatus* (Harris and Kluge 1984), and *Leptotyphlops phenops* was reassigned to *L. goudotii* (Wilson and Meyer 1985). It is noteworthy that neighboring Guanaja, only 12 km due east, was rendered 99% bare by Hurricane Mitch in October 1998, whereas Barbareta's forests experienced very little defoliation and breakage.

Relative to our observations on Roatán, Utila, and Guanaja, reptiles were more abundant on Barbareta and notable were the large numbers of adult (total length > 1 m) iguanas (*Ctenosaura oedirhina*, *Iguana iguana*), clearly a result of the lack of human predation and perturbation. This "ecological peace" is largely a result of care by one of Barbareta's owners who is rumored to shoot at the motors of boats of mainlanders who intend to poach iguanas on Barbareta. In order to estimate herpetofaunal abundance, we established a collecting transect extending northeast from the southern edge of the central portion of the island near the abandoned airstrip. Our transects ran through coastal vegetation and habitats at the water's edge along part of a forest road serving the airstrip, and then turned sharply into a path through thick primary forest habitat (Fig. 1). The following information is an annotated list of new species records for the island.

Basiliscus vittatus (Striped Basilisk). This species was ubiquitous on the island and was seen in all habitats. All sizes and age classes were abundant (LSUPC 4717–24, LSUHC 3693–94).

Ctenosaura oedirhina (Bay Island Spiny-Tailed Iguana). This species was also ubiquitous on the island and several individuals of all age and size classes were observed. It occurred abundantly on the ground and in all types of vegetation (LSUPC 4725–31).

Gymnophthalmus speciosus (Golden Spectacled Lizard). This species was most often encountered moving about in shaded grassy patches along the forest road near the coast, and in the forest leaf litter. Both adults and juveniles were abundant (LSUPC 4868–87, LSUHC 3689–90).

Iguana iguana (Green Iguana). This species was a very abundant component of Barbareta's herpetofauna. Several large individuals (estimated total length > 1.5 m) were observed 3–10 m above ground, crashing through branches of large trees. The majority were observed only in the thickest portions of the forest in large trees and only occasionally on the ground (LSUPC 4690–95). Anecdotal information available locally praises this island as a haven for green iguanas, which are a delicacy on Roatán and no longer abundant there. This is one reason why Barbareta's ownership has

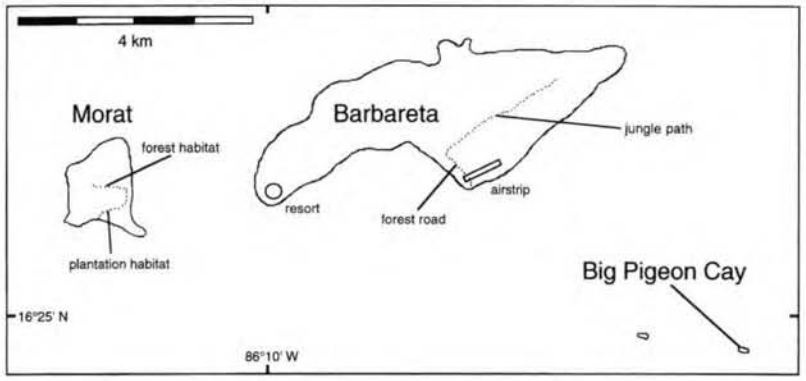

FIG. 1. Map of Barbareta, Morat, and the Pigeon Cays. The dotted line on the larger islands indicates the transects taken.

taken the very strict approach to poaching attempts mentioned above.

Leptotyphlops goudotii (Goudot's Thread Snake). Three specimens of this secretive snake were encountered moving about on leaf litter in shaded conditions. In contrast, on Isla Roatán we found this species to be primarily associated with termite mounds and it was rarely observed moving about during the day (LSUPC 2644–52, LSUHC 3686–88).

Sphaerodactylus millepunctatus (Dwarf Bark Gecko). Several specimens were found during the day moving about on the leaf litter of the shaded forest floor. Others were found within the rotten trunks of various species of trees and beneath various types of surface debris including rocks, logs, and palm fronds. These lizards were observed throughout the transect (LSUPC 4782–84, LSUHC 3695).

Isla Morat

Isla Morat is a small island approximately 0.5 km wide by 1.0 km long (Fig. 1) and lies between Islas Barbareta and Roatán. It is privately owned and settled only by plantation workers on a temporary basis. Some of its coastal areas have been developed for agricultural purposes. Our transect on Morat ran from the plantation habitat at the southern end of the island northeast, then inland for ca. 300 m along a freshly cut path into forest habitat (Fig.1). We visited Morat only briefly from ca. 1600–1800 h. We present the following new records and suspect that with continued surveys additional species will be discovered.

Anolis allisoni (Giant Cay Anole). This species was ubiquitous on the island in both disturbed and natural areas (LSUPC 5796–5804, LSUHC 3696–98, 3703–05).

Gymnophthalmus speciosus (Golden Spectacled Lizard). This species was found moving about through the leaf litter in both disturbed and undisturbed habitats. Only adults were seen (LSUPC 5778–95).

Phyllodactylus palmeus (Palm Leaf-Toed Gecko). This species was found on the ground beneath rocks, logs, palm fronds, and other surface debris in shaded areas, both in disturbed and undisturbed habitats (LSHPC 4769–81, LSUHC 3706–07).

Sphaerodactylus millepunctatus (Dwarf Bark Gecko). Specimens were found during the day moving about on the leaf litter of the shaded forest floor. Others were found within rotten trunks and beneath rocks (LSUPC 4785–87, LSUHC 3710–11).

Sphaerodactylus rosaurae (Rose Bark Gecko). Specimens were found beneath and within rotten trunks of various species of trees in shaded areas in both disturbed and undisturbed habitats (LSUPC 4789–93, LSUHC 3712).

Big Pigeon Cay

Big Pigeon Cay is a small cay no more than 60 m x 20 m in size lying approximately 5 km off the southern edge of Isla Barbareta (Fig. 1). Its periphery consists of sandy beaches and their associated low-growing vegetation. The central portion of the cay maintains scrub vegetation containing small trees and palms. We observed seven individuals (three adults, four juveniles) of *Ctenosaura oedirhina* (LSUPC 5805) within the central portion of the island and their tracks were abundant on the beach. The presence of this species on this cay attests to its capability of overwater dispersal and subsequent colonization.

Acknowledgments.—We wish to thank Pepper Tonsmayer of Isla Barbareta for not shooting at our boats and allowing us access into the interior of the island. We also wish to thank the people of Anthony's Key Resort for their hospitality and their efforts to cater to our special needs. Shawn Hyde, Allan Hyde, and Bucky Weeks were instrumental in facilitating our stay. Collecting permits were issued by Francisco Rosales of the Secretaria de Agricultura y Ganaderia and the Dirección General de Pesca y Agricultura on Roatán. This is Tropical Field Biology Contribution No. 1 from the Department of Biology at La Sierra University.

Pacific Herpetology 2000

GEORGE R. ZUG
Department of Systematic Biology, National Museum of Natural History
Washington, DC 20560-0162, USA
e-mail: zug.george@nmnh.si.edu

2000 was an exciting year for anyone interested in the herpetofauna of the Southwest Pacific. Some would say a great beginning for the 21st Century, but I view the two books and CD before me as a fine culmination of 20th Century research in the Pacific. I wish to comment mainly on Bauer and Sadlier's review of the herpetofauna of New Caledonia; however, I take this opportunity to call attention to P. Ryan's pictorial and textual review of Fijian animals and M. McCoy's revision of his fieldguide to the Solomon Islands reptiles.

The Herpetofauna of New Caledonia, by Aaron M. Bauer and Ross A. Sadlier, with French translations by Ivan Ineich. 2000. Society for the Study of Amphibians and Reptiles, Ithaca, New York. xii+310 pp. Hardcover. US $60.00. ISBN 0-916984-55-9.

At 26x18x2.5 cm and nearly one kg, this book (THoNC) is not a pocket guide or even guide for your fieldpack. Nonetheless, no one interested in reptiles would set foot on New Caledonia without it in their luggage and likely in their hand-carryon because an initial read-through before venturing far from the plane is advisable. The preceding statement identifies my bias. I find THoNC an excellent book. Yes, I can find items on which to claim fault, but aside from those being minor, Bauer and Sadlier met their two goals: 1) to provide a guide for lab and field identification of the New Caledonian reptiles and 2) to identify aspects of biology and taxonomy requiring additional investigation. The book's coverage extends significantly beyond those goals. While I am being laudatory, allow me to extend my appreciation to the SSAR Contributions to Herpetology series' editors for their continuing production of reasonably priced, attractive, sturdy, easily readable, and topical books with few errors of any sort.

If you were attentive above, you noted that I mentioned only an interest in reptiles. THoNC's title says herpetofauna, but it is barely that. NC has one frog, an Australian *Litoria*. The absence of amphibians indicates the oceanic origin of NC and its ancient and continued wide separation from any amphibian source area. Lizards are much better colonizers of oceanic islands, and the first skink and gecko ancestors likely arrived in the early Tertiary. They gave rise to an amazingly diverse and speciose lizard fauna, currently 68 species of geckos (26) and skinks (42), of which 86% are unique to NC. No other island group of comparable size, even land-bridge islands, can match this diversity. Three snakes complete the terrestrial reptilian fauna, and 12 seasnakes and three seaturtles represent the marine elements. An exciting reptilian fauna from any perspective.

THoNC covers this fauna thoroughly. It is organized into eight textual sections (or chapters), a set of color plates, a bibliography, and a gazetteer. THoNC opens with an ecological geography of NC, concisely summarizing geography-topography, vegetation, geology, and biogeography; although concise, the discussions provide the reader with sufficient detail to understand the complexity of the landscape and its history. The second section provides an overview of the natural history of fauna, concluding with brief descriptions of various "herpeto-communities." The third and fourth sections examine conservation issues and man & NC reptiles; this latter section includes an excellent NC herpetological history. The sixth section is the *raison d'être* of THoNC, 180+ pages of generic and species identification keys and taxonomic accounts. Rightly so, Bauer and Sadlier decided that their audience can differentiate a gecko from a seasnake or treefrog, and they provide only keys to genera and species within taxa with multiple members. The familial and generic accounts provide a quick review of taxonomic history and relationship relative to the NC members. Each species account contains a morphological description, distribution, natural history, conservation status, references, and not infrequently remarks on relationships or other items not appropriate to other sections. Each of the sections is organized similarly from account to account and that permits easy comparison of data; information also is presented concisely and thoroughly. Each account is data rich and, critically for an effective guide, includes a distribution map plotting the exact occurrence of vouchered records for each species. There are relatively few textual illustrations. Although I would have preferred more, the number of illustrations is adequate; they are attractive, accurate line drawings and supportive of the adjacent keys or accounts. The next two sections examine sequentially taxa of incidental and questionable occurrences, and erroneously reported taxa. The final textual section reviews subfossil and fossil reptiles. None of these final sections is long; however, the coverage for each taxon adequately supports the assigned status of the species. A section of 24 color photographic plates follows. The first five plates provide a glimpse of the major habitats, and the remaining plates illustrate the majority of the NC herpetofauna, and many of the endemic NC species have more than one photograph to show geographic variation. Most images are roughly 4 x 7 cm; all, but two or three, clearly depict the animal and will assist with species identification.

An important aspect of THoNC are the sectional French translations. Translations, except for the keys, is somewhat of a misnomer. The heading "sommaire français" for them is most appropriate. These summaries conclude all textual sections but the taxonomic one. In the latter section, a French key follows each English one, and each species account has it own French summary. This organization makes the book a ready resource for the French administrators and populace of New Caledonia and will support the conservation of NC flora and fauna.

The next two Pacific items display the artistry of two biologists, who have become professional photographers and yet continue to contribute to the documentation and conservation of Pacific biodiversity. These items are only briefly described to offer a hint of their usefulness as sources of biological information and the delightfulness of their photography—both are fully in color.

Reptiles of the Solomon Islands, by Michael McCoy. 2000. Zoographics: Kuranda, Qld. CD.

The first edition was published in 1980 as a small handbook by the Bishop Museum's Wau Ecology Institute. It was the first fieldguide to this corner of the tropical Pacific since Loveridge's 1945 *Reptiles of the Pacific World*. The Solomons' guide has remained a useful reference for herpetologists working in the Southwest Pacific but was edging out of date with the discovery of new taxa and new details on the biology of the herpetofauna. The original guide had six small color plates. McCoy wished to add many more color plates as well as to revise the text and keys. Photographs were available, but the production of a full color guide can be mind-boggling expensive per book if the print run is small. The solution was to self-produce a CD revision with many color illustrations and make it available to naturalists inexpensively.

The CD's structure is similar to the original guide and is as easy to use, perhaps more so. You access the guide via any web browser, opening the cover page and then navigating from there. Multiple links move you rapidly from a table of contents to keys or species account, or you can simply leaf page by page or jump around in the guide. The keys remain as serviceable as in the original; the text descriptions, distributions, and natural history notes are updated and data-filled; and the photographs are superb. The widespread Pacific taxa are illustrated by one or two photographs, but the Solomon endemic taxa or regional Melansian ones by several photos. My favorite is—I really don't have a favorite; there are too many excellent ones to favor a single photo. I challenge you to just select one!

Fiji's Natural Heritage, by Paddy Ryan. 2000. Exisle Publishing: Auckland, N.Z. 288 pp.

The first edition of *Fiji's Natural Heritage* was published in 1988. It was in part an outgrowth of Ryan's weekly biology articles in the *Fijian Times* and his growing photographic collection of the Fijian flora and fauna. Neither then nor now is it a collection of news articles, but a series of integrated essays on components of the Fijian biota. Its audience is the general public, whether they are a Fijian local or tourist, a businessman or tour guide, a junior high-school student or college professor. Amphibians and reptiles each have separate chapters, but they are only one of many animal and plant groups covered in text and pictures. The content extends from life in the open seas surrounding the Fijian islands to the mountain tops. A biologist can justify the purchase of this coffee-table style book because it contains new biological observations, including a couple in the herp section, as well as for the outstanding photos of Fijian plants and animals, many never photographed previously. This book is about conservation, and its publication was supported by Seacology and the New Zealand government to promote Pacific conservation. Ryan's photos and text show the beauty and depth of the diversity in the Fijian corner of the immense Pacific.

I strongly recommend all three preceding items to anyone doing herpetological research in the Pacific theatre. They are gold mines of accurate biological information, so even if you are a casual visitor to the Southwest Pacific, your visit will be enhanced by reading them beforehand or during your visit.

Herpetological Review, 2001, 32(2), 137–139.

Texas Snakes: Identification, Distribution, and Natural History, by John E. Werler and James R. Dixon. 2000. The University of Texas Press, Austin. xv + 437 pp., 66 color plates, 70 line drawings, 122 maps. Hardcover. US $49.95. ISBN 0-292-79130-5.

ANDREW H. PRICE
Texas Parks and Wildlife Department, Wildlife Diversity Program
4200 Smith School Road, Austin, Texas 78744, USA
e-mail: andy.price@tpwd.state.tx.us

Reviews of most field guides tend to converge toward a common point because the context and content of their subjects are fairly standard; most of the interesting or unique features attendant to their production happen behind the scenes during the writing or publishing phase (ask me sometime over an appropriate beverage about the "missing chapter" in Price 1998). Such is not the case with this unique and oddly-crafted book, a towering achievement in the annals of herpetological natural history and an obvious labor of love by the two authors (as pointed out in the preview on the back cover), who between them possess over a century of first-hand field experience with Texas serpents. John Werler, Curator Emeritus of herpetology at the Houston Zoo, wrote most of the text and Jim Dixon, Professor Emeritus at Texas A&M University, contributed some of the introductory material as well as the checklist, key, and all of the maps. The book had been gestating in the mind of the senior author since his days at the San Antonio Zoo in the late 1940's, with serious work beginning in 1980 and the junior author coming on board in 1984.

The book, as stated in the Preface, was written for a broad readership and directed mainly at those uneducated about snakes in Texas, as well as amateur naturalists and hobbyists. Designed to encourage reporting of natural history information by its readership, this book is a revealing commentary on how little we still know about the life histories of snakes. The book opens with a table of contents and a list of illustrations. Following the preface and acknowledgments comes 43 pages of introductory material which includes sections on conservation, myths and misinformation about snakes, snakebite, a history of Texas herpetology, and a discussion of taxonomic issues. An interesting tidbit occurring on p. 7 is that 4736 citations on Texas snakes (an average of about 67 per species) were published between 1828 and 1996. These are followed by a checklist of and key at the subspecific level to the 72 species native to Texas. The individual subspecies accounts form the bulk of the book, and precede a glossary, bibliography, and indices to common and scientific names. Individual accounts are in turn subdivided into sections labeled description, comparable snakes, size, habitat, behavior, feeding, and reproduction, with the addition of a section on venom where appropriate.

The range maps are far superior to anything that has ever been published on Texas snakes, or any component of the Texas herpetofauna for that matter (with the exception of the privately printed and not yet completed *Atlas of Texas Lizards* by Ralph W. Axtell). They constitute over 10,000 localities representing 46,655 specimens, and were painstakingly compiled by hand. They are a little difficult to see at this size because of the detail included on

the base map and the small size of the locality dots. The dark shapes representing reservoirs can be confusing in some species accounts, especially since a number of the existing ones are not shown. The convention employed in some accounts of presenting the same species map with different shading to represent constituent subspecies ranges is useful but not explained beforehand, creating some initial confusion.

A very nice set of plates accompanies the discussion of aberrant individuals, which follows the section on snake identification. The absence of a general discussion of ontogenetic variation here is surprising to me, especially for a book aimed at the general reader. The remaining photographs illustrating the taxa themselves are grouped together in the middle of the book. They are first-class, as one would expect in anything involving the senior author, and the sequence of shots of death-feigning in *Heterodon platirhinos* is outstanding.

The main body of the book is the species accounts, which provide a gold mine of information for the willing prospector. The accounts are a pleasure to read individually, and the unique writing style transforms the often very dry renderings of morphological detail, habitat descriptions, and behavioral characteristics into smooth prose worthy of London or Melville. The descriptions and comparisons to similar species are for the most part crisp and clear. The text is littered with charming oddities of expression such as "gooey secretions," "puncture the termite's soft body and suck out its fluid contents before discarding the victim's spent carcass," "leafy umbrellas," "streaks away into the brush with a sudden burst of speed that usually leaves its foe momentarily bewildered," "its slender brownish form blending intimately with the layer of dead pine needles that carpets the sandy forest floor," "discharges a musky, cream-colored slime from its cloaca," "may chew viciously as it holds its victim's head in its jaws," "the male is unceremoniously dragged along with her, his engorged, spine-covered hemipenis still firmly held in place within her cloaca," "woodland carnivore," "dashlike spots feebly arranged along the sides of the body as thin, diagonal lines," "the overall effect is that of a daintily jeweled piece of oriental ceramic finished in lacquer," "locks its gaze on the intruder," "bewildering as they may be, a lizard's evasive tactics are brilliantly matched at every turn by the rapid maneuvers of its ophidian pursuer," "braided their trunks together in a corkscrew embrace," and much more; enough, perhaps, to constitute their own number in the Smithsonian Herpetological Information Service series. All add to the overall charm, if not the scientific content, of the book.

It may be surprising to learn, given the preceding comments, that I generated six pages of notes on specific caveats while reviewing this book. Some are factual errors, while others are matters of interpretation and misplaced inference. Space constraints prevent me from discussing them all, but their cumulative effect left me weary, somewhat annoyed, and wondering if anyone reviewed this book prior to its publication (no one is acknowledged as having done so).

Typographical errors are few but nonetheless surprising, as most involve people's names. Thus we have Busak (= Busack), Cantanella (= Cannatella), and Degengardt (= Degenhardt) in the acknowledgments, and toboso (= tobosa) and Gehlback (= Gehlbach) on p. 248. An interesting fact, given the number of published citations on Texas snakes mentioned above, is that the bibliography contains only 402 citations, not all of which are on populations actually occurring in Texas. Perhaps this reflects the authors' extensive first-hand knowledge of their subject. At least two primary natural history papers were missed, however, Sawyer and Baccus (1996) on *Bogertophis* and Rudolph and Burgdorf (1997) on *Pituophis ruthveni*.

Anthropomorphisms in this book are legion. We have *Elaphe bairdi* "apparently aware that they are not easily detected [therefore] mov[ing] rather leisurely" over the ground (p. 106); "discarded" rodent burrows (p. 118); predation by *Farancia* on *Amphiuma* described as "savage, unrelenting, and vicious" (p. 124); *Heterodon nasicus* "nonchalantly" and "leisurely" crawling away after death-feigning (p. 130); *Lampropeltis getula* described as "slothful" (p. 157) while on the same page their infrequent predatory attacks on rattlesnakes described as "vengeful," "violent," and "savage;" "sinister" *Nerodia sipedon* (p. 221) and "insolent" *Crotalus atrox* (p. 370); a reference to the rostral scale of *Salvadora grahamiae* as "unnatural" (p. 252); "even the boldest adversary [of *Crotalus molossus*] sens[ing] the menacing implications of the tongue's slow, deliberate movements" (p. 391), and "infant" snakes of several species scattered throughout the text.

Other miscues reflect to this reader the lack of a careful editorial review by someone knowledgeable about the subject matter and/or by editors at UT Press. On p. 4 we are told that native species of snakes are unaggressive, a statement later contradicted in several species accounts. Among those listed on pages 6–7 as still involved in herpetology are Ben Dial and W.W. Milstead, both deceased. Forests of juniper, ponderosa pine, and oak are referred to on p. 10 as "alpine." Snakes in the genus *Coniophanes* frequently suffer from "tail rot" (p. 89), an unexplained malady. The diameter of a home range is described as being "twice as long" as another on p. 92. On p. 177 the western smooth green snake is referred to as the western smooth snake. Prey of *Salvadora grahamiae* include "whiptail, race runner and scaly lizards;" whiptails (genus *Cnemidophorus*) include the racerunner (*Cnemidophorus sexlineatus*) and, since all lizards are 'scaly,' the authors undoubtedly mean to refer to 'spiny' lizards (genus *Sceloporus*). Included prey of *Crotalus viridis* are "striped gophers" and "slum larks;" I'm confident the former refers to ground squirrels of the genus *Spermophilus*, but neither I nor a couple of ornithologists I've asked know what a "slum lark" is. The habitat of the massasauga is characterized (p. 406) as "estuarine." Cases where the range maps do not match the text descriptions include the nominate and *gloydi* subspecies of *Heterodon nasicus, Lampropeltis getula splendida, L. triangulum celaenops, Nerodia erythrogaster transversa, Regina grahami*, and *Sistrurus catenatus edwardsi*. In discussing the family Elapidae readers are told that there are 54 species of American coral snakes grouped together in the genus *Micrurus* (there are currently 61 recognized species of *Micrurus* and two other genera of coral snakes one of which, *Micruroides*, occurs in the United States; Roze 1996).

More troubling, perhaps, are misinterpretations of published papers. Gehlbach and Baldridge (1987) are cited as providing evidence that *Leptotyphlops dulcis dulcis* possess the ability to climb tree trunks, when in fact the authors of this paper state that these snakes are deliberately carried by owls to their nests. Carr (1940) is cited in the *Nerodia fasciata pictiventris* account as stating that these snakes feed on breeding aggregations of "barking frogs" in

Florida. Barking frogs (*Eleutherodactylus augusti*, Leptodactylidae) do not occur naturally in Florida; they do occur in Texas, but not within the range of this snake. Carr (1940) in fact referred to *Hyla gratiosa,* which he called "bell-frogs," and the current common name for this species is the barking treefrog. One of the prey species attributed to Greene et al. (1994) for the Concho watersnake is the "redhorse shiner;" there is no fish in Texas referred to by that common name, whereas Greene et al. (1994) actually referred to the gray redhorse (*Moxostoma congestum*), a fish very different from shiners (*Cyprinella* and *Notropis*) found in the Colorado River drainage.

Don't read this book for content on current taxonomic practices, evolutionary species concepts, or insightful discourses on evolutionary ecology; the modicum presented is muddled at best. For example, the "western hog-nosed snake alliance" is referred to in the Mexican hog-nosed snake (ssp. *kennerlyi*) account on p. 139. The species *Heterodon nasicus*, to which this common name refers, is a separate entity on its own evolutionary pathway, not a conglomerate made up of discrete particles as one might find in a bag of marbles. The term "niche" is used on pp. 97 and 374 as a discrete place rather than as the term referring to the multidimensional state space encompassing a species' entire ecological characteristics; a term such as "habitat" or "microenvironment" would be more appropriate. Also on this page the terms "species" and "subspecies" are used for the same taxon in the same paragraph. The phrase "two closely related subspecies of *Sonora*" is used in the Great Plains ground snake account; the correct taxonomic hierarchy has genera having species, whereas only species contain subspecies.

I learned a number of things about Texas snakes (or at least that I don't remember knowing) by reading this book: that two of the three subspecies of *Diadophis punctatus* occurring in Texas lay eggs in advanced stages of development; that individual *Elaphe obsoleta* may hibernate underwater in old wells and are well-equipped to remain underwater for more than an hour because of large and numerous air pockets in the lung; that *Heterodon nasicus* find reptile eggs to eat by using the fresh odor of laying females as a location marker; that combat dances between male *Pituophis catenifer* are sometimes over food, not mates; that *Micrurus* thrash about erratically during defensive reactions, occasionally leaving the ground when they do so; that *Crotalus viridis* venom is more virulent than that of *C. atrox*; that burrowing owls are a natural prey item of both *C. atrox* and *C. viridis*; and that toads (*Bufo*) are likely an important dietary component for *Sistrurus catenatus edwardsi*.

The frequent references to scent gland secretion as "loathsome material" or one of several equally pungent phrases seems to me at best an exaggeration and at worst inimical to the favorable treatment of snakes by members of the target audience of this book. Similarly, statements that specimens of *Arizona elegans, Cemophora coccinea*, and other species are "frequently" unearthed by farmers plowing their fields and that this is an indication that these species don't burrow deeply during the active season are meaningless without a frame of reference. To state that the estimated 1400 bites from *Crotalus atrox* inflicted annually on humans have caused a "serious negative impact...on the state's human population" (p. 375) is simply inaccurate.

While UT press is to be commended in some senses for publishing such an unusual book, the structure chosen by the authors has resulted in considerable repetitiveness in the text, both between sections in an account and between accounts. The text could easily have been cut by 1/3 without losing any of its value. My major criticism of this book, however, is that countless statements herein are made as statements of fact integral to the ecological and evolutionary characteristics of a given taxon when they appear to be based (for lack of citation) on no more than a single reference or casual observations and impressions, rather than on careful long-term observations in the field or controlled experiment. I find this most unfortunate in a book aimed at the novice natural historian and people misinformed or uneducated about snakes.

The glossary is very abbreviated, and a number of terms in the text are not defined that should be; these include crown, Jacobson's organ, ambient, trunk, vole, medial, nape, digitaloid, tubercles, papillae, and bleb. In addition, some definitions provided are not very useful; for instance, 'microhabitat' is defined as "a small piece of an animal's habitat."

Some of the repeated authors' names in the bibliography are lined and others are not, and there are occasional problems with indentation of the individual entries. The bibliography would be much easier to read if each citation was separated by a spacer line or a hanging indentation as is commonly done in other books of this kind.

In spite of its shortcomings, this book is a must for anyone interested in Texas herpetology, and will remain the authoritative treatise on Texas snakes for decades to come. It should be in every public, school, and university library as well. The maps and photographs alone are worth the price of the book, which is a bargain thanks to a generous grant from the Zoo Friends of Houston, Inc. Buy it, read it leisurely, and enjoy!

Modern systematic practices often involve molecular or morphological comparison of extant taxa exclusively. But to fully understand the evolution of a higher taxon requires knowledge of its history, and this can only be obtained from the fossil record. This truism is amply demonstrated by a brief perusal of *Fossil Snakes of North America*, which treats the fossil record of all snakes of the continent (north of Mexico), extant and extinct. This book documents the evolutionary rise and fall of various snake families, most of which have living relatives somewhere in the world today, though not necessarily in North America. A few of the taxa covered are entirely extinct. What makes this book unique is its coverage of the fossil record of living snake species, as well as their extinct predecessors. It differs from the *Handbuch der Paläoherpetologie* (Fischer Verlag) series in that it provides revised diagnoses and descriptions for many extinct taxa of fossil snakes as well as detailed descriptions of type material and associated elements.

J. Alan Holman is uniquely qualified to write on fossil snakes. Indeed, much of this book is a synthesis of an important part of his life's work detailing the fossil record of the extant orders of amphibians and reptiles. Holman is one of a select few individuals who has worked extensively with snake fossils, and his contribution has been prodigious as can be seen from the bibliography. Entries for which Holman is first or sole author occupy nearly five pages and the publication dates span a full four decades. Thirty-one of the 108 entries under his name deal exclusively with fossil snakes.

This book is divided into four chapters and a brief epilogue. Chapter One deals with topics that serve as an introduction to the rest of the book. It begins with a précis of the evolutionary history of snakes in North America, and a brief history of fossil snake studies. These topics are followed by a helpful discussion of features of the snake skeleton that are used to identify snake fossils. Special emphasis is placed on vertebrae, which are the most commonly found fossils. A standardized terminology that is used throughout the book is introduced here. Not everyone will agree with the terminology chosen, however. For example, Holman refers to the portion of the trunk that bears hypapophyses in all snakes as the cervical region, whereas I prefer Hoffstetter and Gasc's (1969) conclusion that the cervical region is unrecognizable in limbless squamates because landmarks of the cervico-thoracic boundary become dissociated from one another as the skeleton becomes more elongate. However, as Holman clearly defines his meaning in using this term, and the definition is easily applied, readers may find it more practical to use this term than any more cumbersome descriptions.

Chapter Two consists of systematic accounts of snake taxa described from the fossil record of North America. This will be the most useful chapter to future students of snake paleontology because revised diagnoses of most extinct snake species from North America and detailed descriptions of type material and representative skeletal elements are provided. The fact that the original author of many of the snake genera known from pre-Pleistocene times in North America has here compared and revised the descriptions of contained species will be of immense value, as the addition of new species to a genus will inevitably change one's perception of the type species. Holman also revises diagnoses and descriptions of taxa originally named by other authors, but these changes are primarily intended to produce conformity of terminology. One problem with the design of this chapter is that there are few direct references to the literature. To find all of the references about a given taxon that are in the bibliography one must consult a list of localities under the subsection entitled "Other Material." Here, the age and the state from which each fossil find was reported must be noted, and a locality number referring to an entry in Chapter Three determined. All three of these pieces of information are needed to look up the entry in Chapter Three that deals with the deposit from which the taxon is recorded, and only there will a full list of references to the desired bibliographic entries be found.

Chapter Four is probably the most interesting chapter in the book as it provides a synthesis of material in the preceding chapters and allows one to follow temporal changes in the snake assemblages of North America. The chapter moves through the fossil record, epoch by epoch, detailing the rise and fall of taxa at the generic level. Interpretations of the paleoecology of the assemblages discussed are based on comparison with modern taxa that are the nearest relatives of the fossils. A section entitled "Snakes in the Ice Age," which reviews theories explaining the relative stability of Quaternary snake communities concludes the chapter. Several interesting examples of the effects of Pleistocene glaciation on the distribution of snakes are provided. Most of these are in the form of groups of extralimital records, but a detailed analysis of the repopulation of the state of Michigan after the retreat of the Wisconsinan Glacier is particularly interesting.

An epilogue lamenting the current decline of snake populations and their habitats ends the book. Holman notes the irony of this decline in such a geologically young and vigorously evolving group of organisms as snakes.

The bibliography contains a wealth of references on fossil snakes and the localities where they were found. Some of the references are quite obscure, and in most respects the bibliography appears to be complete. Thus, it is a bit odd that in Chapter Three, when discussing *Paraepicrates* and *Pseudoepicrates* which are both treated as valid genera, Holman does not reference Kluge (1988). In this note, Kluge synonymizes *Paraepicrates* with *Lichanura*, and considers *Pseudoepicrates barbouri* a junior subjective synonym of *Boa constrictor*. These actions are not mentioned by Holman. This is all the more surprising because Kluge acknowledges Holman as a reviewer of the manuscript.

Though Holman has achieved a commendable uniformity of descriptive terminology, he has not done the same for the images of vertebrae presented, and this is, perhaps, the book's weakest point. Most of the images of snake vertebrae in the book, largely

pen and ink drawings, were extracted from previous Holman publications. While some are of high quality, others are not. Many were obviously drawn without the aid of camera lucida and the illustrated proportions are unrealistic. The following examples are especially noticeable: Fig. 76 is a distorted image of a modern *Heterodon platyrhinos* vertebra; in Fig. 94 the neural arch of a *Masticophis flagellum* vertebra extends too far beyond the postzygapophyseal facets in ventral view and this view appears longer than the dorsal view of the same vertebra; in Fig. 117, the condyle of *Rhinocheilus lecontei* is exaggerated, while in Fig. 118, the zygosphene of *Salvadora grahamiae* is inflated. Whereas these illustrations provide one of the few useful synoptic collections of images of fossil and recent snake vertebrae, it would have been more useful to have images of consistently high quality.

An unusual aspect of *Fossil Snakes* is its attempt to appeal to a general audience. The center of the book contains some excellent color plates depicting living examples of snakes of the various taxa discussed in the book. Whereas these photos may be useful to the neophyte, I wonder how many people who have the patience to read dozens of pages of descriptions of vertebrae do not already know what these animals look like. Except for the first three plates, most of the photos have little relevance to the fossil record.

Despite these few criticisms, I recommend this book highly as both a milestone in the field, and a critical reference for anyone interested in the paleontology, evolution, or ecological history of North American snakes. It will also be an important general reference for other vertebrate paleontologists and herpetologists. Its greatest use will be as a guide to those with unidentified snake fossils in hand.

Acknowledgments.—I thank J. Pruetz and N. Woodman for helpful comments on this manuscript.

The islands of the southwestern Indian Ocean are among the most herpetologically interesting in the world, supporting a diverse, highly endemic fauna of often bizarre and spectacular animals. The amphibians and reptiles of Madagascar, in particular, are currently being investigated by numerous researchers whose studies have yielded a continuous stream of new species descriptions, rediscoveries, and phylogenetic revisions. Until now the only single volume treatments of the herpetofauna of Madagascar were the two editions of *A Fieldguide to the Amphibians and Reptiles of Madagascar* (Glaw and Vences 1992, 1994) and only *Amphibien und Reptilien Madagaskars, der Maskarenen, Seychellen un Komoren* by Henkel and Schmidt (1995) also dealt with the fauna of the Seychelles, Mascarenes, and Comores. Whereas the former volumes covered the entire Malagasy herpetofauna at some level, the later work highlighted selected species only—chiefly those with which the authors had experience in the field and/or the terrarium.

This book is a faithful English translation of Henkel and Schmidt's (1995) German original. The format of the English edition is somewhat larger than the original, but the layout follows it closely, and the same photographs have been reproduced. There seem not to have been any significant updates made to the text since the original edition. This is evidenced in the bibliography, which covers works through 1993 and lists a 1994 publication as "in preparation." However, some species accounts have been updated by the addition of a "new taxonomy" listing under the species name as published in 1995. In addition, a checklist of species, updated as of 31 December 1997, is provided at the end of the book. Unfortunately this list does not take into account the generic revisions of some groups and, in the case of the Mascarenes, some of the names used are decades out of date. Further, the ongoing work of numerous herpetologists in Madagascar and, to a lesser extent, the other island groups have already made these lists obsolete. Literally dozens of new taxa have been described from the region since 1997.

The book begins with a 25-page overview of the islands covered. Madagascar is the clear emphasis here, with a discussion of 14 pages covering the geology, vegetation, climate, and fauna, supplemented with habitat photographs and a useful map, illustrating numerous localities mentioned in the text. The bulk of the book is devoted to representative species accounts, arranged by family. Each account is one page in length and includes: Latin name, authorship and date of description, type locality, distribution, habitat, size, distinguishing features, biology, and vivarium care. Each of the 240 featured species is illustrated by a color photograph. The text appears to be reasonably accurate, although distributions for many forms are now out of date and the stated type localities do not always match those in the original descriptions exactly. The photos are generally good to very good, but there are problems with depth of field in some cases (e.g., *Tachycnemis seychellensis*, p. 42; *Brookesia bonsi*, p. 98; *Furcifer belalandaensis*, p. 126; *Lygodactylus miops*, p. 176; *Millotisaurus mirabilis*, p. 177), and composition in others (e.g., *Sooglossus seychellensis*, p. 45; *Calumma gallus*, p. 113; *Mabuya aureopunctata*, p. 263).

The Malagasy bias is shown at the outset of the species accounts, as the section dealing with caecilians (limited in this region to the granitic islands of the Seychelles) covers less than one page, provides no individual species accounts, and is not illustrated. In contrast, 55 species of frogs are highlighted, of which three are from the Seychelles, one (introduced) in the Mascarenes, one widespread on Indian Ocean islands, and the remainder are Malagasy. Turtles are represented by seven species including four Malagasy tortoises,

the Aldabra giant tortoise, and two pelomedusids. *Crocodylus niloticus* is also included (note that vivarium care is omitted for this species and the Aldabra tortoise!).

Chameleons are among the best represented taxa, with 40 (of 60+) regional species covered. Six oplurid lizards are treated, as is the agamid *Calotes versicolor* (introduced in the Mascarenes). The Malagasy radiation of gerrhosaurids is represented by 11 species accounts. While this was a reasonable representation of taxa in 1995, the number of recognized species in the group has recently increased substantially. Gekkonids occupy the largest segment of the book, a full 90 pages. Like chameleons, also popular among herpetoculturalists, the species accounts of geckos are often provided with somewhat more detailed vivarium care information than are those of other groups. Eighty-two gecko taxa are treated, with a heavy bias (52 forms) towards the colorful species of day geckos, *Phelsuma*. In contrast, the tiny *Lygodactylus* geckos, which also have an impressive Malagasy radiation (at least 22 species) are represented by only two species (plus the closely allied *Millotisaurus*). The *Phelsuma* section differs from all others in the book in providing a separate set of maps to show distributions. It also includes two species accounts for extralimital species, *P. anadmanense* from the Andaman Islands in the Bay of Bengal, and *P. parkeri* from Pemba Island, off the coast of Tanzania.

Given their high diversity in the Madagascar region (approximately 60 species), skinks are probably the least well covered reptile group, with only 14 species accounts. Of these, the only non-Malagasy taxa, *Mabuya seychellensis* and *M. wrightii*, both from the Seychelles, lack vivarium care notes. Snakes fare slightly better than skinks with 23 species (of approximately 75) covered. The coverage is uneven, however, with no accounts for the blind snakes or sea snakes. The quality of photographs is somewhat lower on average for snakes than for frogs or lizards and vivarium notes are lacking for seven of the featured taxa.

The book finishes with a brief overview of selected Malagasy parks and reserves (including information on entry permits and guides), and the updated list of species mentioned above. The bibliography of 110 works includes a variety of sources, including many general works, species descriptions, and herpetocultural papers. Much of the relevant technical material, however, is lacking.

A major plus for the book is that it presents photos of a large number of interesting, often bizarre forms that have rarely been illustrated in color before (e.g., *Rhombophryne testudo, Brookesia vadoni, Ichycyphus perineti*), including many recently described species. Photographic quality is generally good to very good and even the marginal photographs generally are quite useful for identification. Virtually all images are at least 60 x 80 mm, and most are larger, making them much easier to see and use than the tiny photos in Glaw and Vences (1992, 1994).

I am not in a position to judge the quality of the vivarium notes provided by the authors, but I assume that these are accurate. I did note a number of minor factual errors throughout the text, however. On p. 1 the authors claim a separation of Madagascar from Africa of about 165 million years ago and refer to this as the early Cretaceous (this age would, in fact, be late Jurassic). On p. 4 it is stated that the northern tip of Madagascar lies just south of the Tropic of Capricorn; of course, this is in error for the southern tip. On p. 162 it is claimed that the Gekkonidae evolved from the Jurassic ardeosaurids and bavarisaurids about 50 million years ago; 150 million years ago would appear to be more likely. Not surprisingly, given the age of the German original of the book, a list of the gecko genera occurring in the region does not include some newer taxa, such as the genus *Matoatoa*, erected for the Malagasy "*Phyllodactylus*" by Nussbaum et al. (1998). Inexplicably, however, the list includes both *Gymnodactylus* and *Cyrtodactylus* from the Mascarenes. In reality, both generic names were previously applied to the same species, which was transferred to the new genus *Nactus* (not listed by Henkel and Schmidt) by Kluge (1983). Finally, I note that the photo of *Hemidactylus frenatus* appears to be incorrectly identified, as the illustrated specimen is highly tuberculate, a feature common to other regional *Hemidactylus*, but not this introduced species. Comparable errors may exist for other groups dealt with in the book, but overall, these errors are well within the average encountered in herpetological books intended for a general audience.

Although some specialist information is provided in this volume, it is clearly intended for a popular or semi-popular audience. Despite its drawbacks (see Nussbaum and Raxworthy 1996), the book by Glaw and Vences (1994) is a more detailed and reliable source of technical information for specialists, or those with a particular interest in Malagasy frogs and reptiles. These authors provide keys, a reasonably complete bibliography, sonograms, type specimen data, and point distribution maps for a comprehensive range of taxa. Henkel and Schmidt, on the other hand, make no claims to be comprehensive and their focus on chameleons and geckos over skinks and snakes, as well as the presence of vivarium care notes throughout, highlights the fact that the book was written principally for herpetoculturists. Nonetheless, this is not a "keeper's" book. Rather, the authors have tried to provide an introduction to the natural history of Indian Ocean island frogs and reptiles to readers who may know the animals only in a captive setting. In this they have succeeded. The book's photos will also make it useful to professional herpetologists who are unfamiliar with the Malagasy fauna. Those seeking information regarding the herpetofauna of the Seychelles, Mascarenes, and Comoro Islands, however, may be disappointed, as many groups (especially caecilians) are inadequately represented.

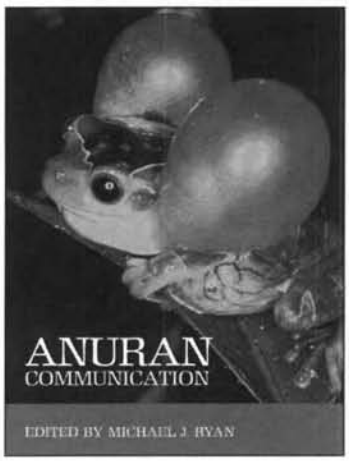
Announcing a New Herpetological Circular
from
the Society for the Study of Amphibians and Reptiles

Amphibian Monitoring in Latin America: A Protocol Manual
Monitoreo de Anfibios en América Latina: Manual de Protocolos

Karen R. Lips, Jamie K. Reaser,
Bruce E. Young, and Roberto Ibáñez



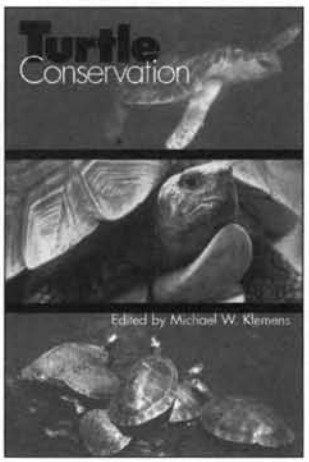
HERPETOLOGICAL CIRCULAR 30

This new publication provides a very practical and bilingual manual for conducting amphibian monitoring. The manual is aimed at South and Central America, but provides many techniques that can be applied in any monitoring situation. Written by Latin American experts and tested throughout the region. Approx. 125 pp. ISBN 0-916984-58-3. July 2001

Prices: Prepublication (*SSAR members only*)		After October 31, 2001	US $ 13.00
first copy	US $ 10.00 postpaid	**Shipping** : First copy	US $ 2.00
additional copies	US $ 8.00 postpaid	Additional copies	US $ 1.00

Send orders to: Dr. Robert D. Aldridge, SSAR Publication Secretary, Department of Biology, Saint Louis University, 3507 Laclede Ave., St. Louis, Missouri 63103 USA. *Telephone* 314-977-3910: *fax* 314-977-3658; *email*: ssar@sluvca.slu.edu. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership deatails and a complete list of Society publications can be obtained on request to Dr. Aldridge.

Anuran Communication



Edited by
Michael J. Ryan

Twenty five scientists from around the world review the most recent advances, addressing vocal, visual, and chemical signals, the physiology and energetics of their production, neural processing, and evolutionary implications.

86 b&w illus., 21 tables, 3 b&w photographs • 264 pp.
8.5 x 11" • Hardcover $50.00

Turtle Conservation

Edited by
Michael W. Klemens
Foreword by Nat B. Frazer

"For those involved specifically in chelonian conservation, it . . . will provide a benchmark for directing future efforts to save the world's dwindling turtle populations."

—*Bulletin of the Chicago Herpetological Society*

8 b&w photographs, 7 b&w illustrations • 344 pp.
6 x 9" • Hardcover $40.00

Smithsonian Institution Press
P.O. Box 960 • Herndon, VA 20172 • 800.782.4612

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, and Legislation & Conservation should be sent directly to the appropriate section editor. Send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, Herpetological History, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without consulting the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 700	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2001 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 27–31 July 2001

Society for the Study of Amphibians and Reptiles
2001 Annual Meeting

together with

The Herpetologists' League

27 – 31 July 2001
University Place Conference Center and Hotel
Indianapolis, Indiana, USA

Keynote Address: "Herps and Hopes: Africa in a New Millenium," by Bill Branch, The Hepetologists' League Disntiguished Herpetologist for 2001 (Port Elizabeth Museum).

Symposium: "Amphibian Population Declines." *Organizers:* David M. Green, McGill University (czdg@musica.mcgill.ca) and Karen Lips, St. Lawrence University (klip@music.stlawu.edu).

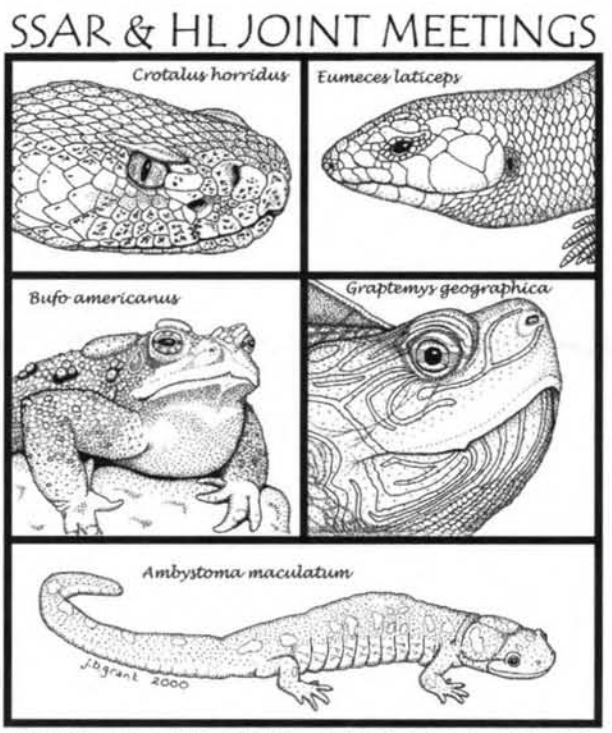
Symposium: "Herpetological Research in Zoos: The Academic Connection." *Organizers:* John D. Groves and Hugh R. Quinn, Cleveland Metroparks Zoo (hquinn@ix.netcom.com).

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

Student Travel Awards: Ten Sherman A. Minton student travel grants of US $200 each will be available for SSAR members. Refer to page 201 of the December 2000 issue of *HR* for details.

Student Paper Awards: Henri Seibert prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the official Meeting Announcement for details.

Social Activities: General Reception in the University Place Ballroom, SSAR Herp Silent Auction, Graduate Student Reception, Sunday night Barbecue Dinner and Auction, Graduate Student Reprint & Book Scavenge, Herpetological Quiz.



Multimedia Presentations: "Amphibians of the Appalachians," and "Herpetology of the West," by David Dennis and Eric Juterbock. President's Travelogue slide presentations by Patricia Burrowes (Puerto Rico), Tim Halliday (South Africa), John Wilkinson, Ross Alford (Australia), Hinrich Kaiser (Southeast Asia), and Michael Lannoo (Antarctica).

Live Animal Exhibit: Live amphibians and reptiles of Indiana will be on display and available for photography.

Costs: Preregistration US $240 regular, US $175 student, US $120 accompanying person. After June 1, 2001, costs are US $295, US $200 student, US $145 accompanying person.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Further Details: Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of the participating societies. Overseas members wishing to receive this information may do so by contacting Henry R. Mushinsky, Local Chair, Department of Biology, University of South Florida, Tampa, Florida 33620, USA; e-mail: mushinsk@chuma1.cas.usf.edu or telephone 813/974-5218. Please visit the meeting web site at http://www.ukans.edu/~ssar/ind.html for additional and updated information.

About Our Cover

The composite photograph on the cover was made from a series of video frames of an African clawed frog (*Xenopus laevis*) larva surfacing to breathe air. The tadpole is approximately Gosner stage 32 and 3.6 cm in total length. The numbers in the upper left-hand corner indicate elapsed time in milliseconds.

The pictures were taken with a Kodak Ektapro high speed video camera at 500 frames/sec. The camera was equipped with a 105 mm macro lens. Multiple lights placed obliquely overhead were used to illuminate the tadpole and to provide a dark field effect. In addition, a black cloth was wrapped around the aquarium to further darken the background.

Several tricks were used to ensure that tadpoles were in focus when they broke the water's surface. The camera was prefocused on a small area of water just inside the wall of the aquarium. The tadpoles were then constrained to breathe in that area by an inverted half-funnel made of mesh netting anchored to the bottom and front wall of the aquarium. This structure directed tadpoles toward the front of the aquarium as they surfaced to breathe air. The temperature at the water's surface was allowed to rise as high as 28°C and nitrogen was intermittently bubbled into the water to drive the pO_2 down. Both factors encouraged the tadpoles to breathe air.

Overhead video of tadpoles surfacing to breathe air also was taken, using a 45° mirror mounted above the aquarium, and have been published elsewhere (Wassersug and Yamashita 2000. The mechanics of air-breathing in anuran larvae: implications to the development of amphibians in microgravity. Adv. Space Res. 25:2007–2013). Additional information on the photographic methods are provided in Wassersug and Yamashita (*In press*. Plasticity and constraints on feeding kinematics in anuran larvae. Comp. Biochem. Physiol.).

The video sequence reveals two surprising aspects of the tadpole's behavior. First is the speed of the action. The tadpole in this particular sequence spent less than 80 msec with any part of its body above the water's surface. This is, literally, faster than a blink of the eye.

The second surprising aspect of this maneuver is how tightly the tadpole turned. The radius of curvature for the loop in the base of the tadpole's tail, seen at 110 msec, is only a tenth the length of the tadpole. With turns so sharp and tight, the tadpole must swim past its own tail. At 100 and 110 msec the tip of the tail can just be seen sticking out from behind the tadpole.

As a result of the fact that the tail goes behind the tadpole, the thrust generated by the tail is no longer purely along the long axis of the tadpole. Torque is generated, which causes a rolling action on the long axis of the tadpole. In the sequence shown here, this results in a 90° roll for a 180° turn. Note that in both the first and last frames the tadpole's right eye is closest to the viewer. If the turn was a pure yawing (sideways) motion, as suggested at 80 and 90 msec, then upon descent the tadpole's left eye should be closer to the viewer.

The overhead views revealed that *Xenopus laevis* larvae do not begin to open their mouths until their mouths are fully above the water's surface, yet start to descend with their mouths still open. This is in contrast to *Rana catesbeiana* tadpoles, which begin to open their mouths upon ascent, and before they have cleared the water's surface, but then close their mouths completely before the mouth is fully submerged (Wassersug and Yamashita, *op. cit.*). It is not known how tadpoles of either species know when to open their mouths so as to get a mouth full of air and not one of water.

The photo sequence is the work of **Masamichi Yamashita** and **Richard Wassersug**. Yamashita is a Professor in the Division of Systems Engineering at the Institute for Space and Astronautical Science, in Sagamihara, Japan. He has studied a variety of aspects of amphibian behavior and development, particularly as they relate to altered gravity.

Wassersug's primary interest is in the evolution and behavior of tadpoles. He is a Professor in the Department of Anatomy and Neurobiology at Dalhousie University, in Halifax, Nova Scotia. However, this year he is on sabbatical and dividing his time between a post as "Scientist in Residence" at the Discovery Channel in Canada and a "Visiting Scholar" position at the Center for Advanced Studies in the Space Life Sciences, at the Marine Biological Laboratory, Woods Hole, Massachusetts.

Yamashita (left) and Wassersug (right) are shown here collecting frogs in February on Amami Island, Japan. Below their feet, and not shown in the photograph, is a clump of freshly laid *Rhacophorus viridis* eggs. These eggs are laid in foam nests above the water line. The tadpoles wash into the water after hatching.

Separation, imaging, and various compositional challenges were handled by **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

Kennedy Student Award Committee Annual Report

The Kennedy Award Committee has completed its work for Volume 34 of the *Journal of Herpetology*. The Committee has selected "Nest site selection, larval hatching, and advertisement calls of *Rana arathooni* from Southwestern Sulawesi (Celebes) Island, Indonesia" by **Rafe M. Brown** and **Djoko T. Iskandar** (Vol. 34:404–413). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

The Committee encourages each student member of the Society to submit their work to the *Journal*, and encourages each regular member who supervises the work of students to encourage his/her students to submit their work to *JH*. Kennedy Award Committee members were Robin Andrews, Terry Schwaner, Lynnette Sievert, Sam Sweet, and Robert Gatten, Jr. (Chair).

SSAR Grants-in-Herpetology Committee Annual Report (2001)

An award in the amount of US $500 was made to each of the following individuals:

Field Research.—**John P. Labonte**, University of California, Santa Barbara. Project title: "Ontogeny of foraging behavior in the Southern Pacific Rattlesnake (*Crotalus viridis helleri*)."

International.—**Jaime Zaldivar-Rae**, Universidad Nacional Autonoma de Mexico. Project title: "Function of female attendance by males of the teiid lizard *Cnemidophorus costatus*."

Conservation.—**Glen M. Lubcke**, California State University, Chico. Project title: "Movements, habitat use, and mortality rates in the Western Pond Turtle (*Clemmys marmorata marmorata*) at the Sacramento River, Butte Co.,California."

Bibliographic Research.—**Christopher A. Sheil**, University of Kansas. Project title: "Bibliographic survey of type-descriptions of living and fossil amniotes, particularly Reptilia."

Herpetological Education.—**Robert N. Reed**, Auburn University. Project title: "Conservation of Sea Kraits (*Laticauda*) via school and community outreach in Vanatu."

Laboratory Research.—**Todd Castoe**, University of Texas at Arlington. Project title: "Evolution of the Middle American jumping vipers, *Atropoides* Werman 1992, inferred from nuclear and mitochondrial DNA sequences."

Travel.—**Jonathon C. Marshall**, Brigham Young University. Project title: "Applying the cohesion species concept to the *Sceloporus grammicus* complex."

2001 Grants-in-Herpetology Committee.—Chair: Joseph R. Mendelson III. Reviewers: Sharon Wise, Michael Keck, Tod Reeder, Joseph Slowinski, W. Bryan Jennings, and Ronald Gutberlet.

SSAR congratulates the 2001 GIH recipients and thanks the committee members for their efforts.

WILLIAM DUELLMAN'S "HYLID FROGS" TO BE PUBLISHED AT INDIANAPOLIS MEETING

DAVID DENNIS'S WATERCOLORS WILL BE SOLD

SSAR's expanded edition of William Duellman's "Hylid Frogs of Middle America" will be issued on the occasion of the upcoming herpetological conference in Indianapolis, July 27–31. Full details about this spectacular new book were published in the March 2001 issues of *Herpetological Review* (pages 4–5) and *Journal of Herpetology* (page 172). Prepublication prices to SSAR members ($95 for the two-volume, clothbound set, with 1170 pages and 94 plates of which 46 are in color) will remain valid only until the meeting. Thereafter, the price to all will be $125.

A celebration to mark the publication of the new edition will be held on Sunday, July 29, from 3:30 to 5:00 PM in room 208 of the Conference Center. All meeting registrants are welcome to attend the reception, just upstairs from where the paper sessions will take place. **Bill Duellman and Dave Dennis will be present.**

The original watercolors painted by David Dennis for the new edition will be on display and available for sale at prices ranging from $150 to $500 each. Proceeds from these sales will be used exclusively to underwrite the production costs of the book.

NEWSNOTES

MCZ Renovation

The Herpetology Department at the Museum of Comparative Zoology, Harvard University, has been awarded a collections improvement grant by NSF, which will fund physical renovation of two of our five main specimen storage rooms. The renovation will enhance storage capacity and quality for much of the collection and improve the work environment for curatorial staff and visiting scientists. Work will commence summer 2001 and require approximately one year to complete. Much of the herpetological collection will be placed in long-term storage during this time and will be unavailable for shipment as loans or for inspection by visitors. This includes virtually all alcohol-preserved amphibians, snakes, and many turtles, plus the entire osteological collection

(dried skeletons and cleared-and-stained specimens). Anyone planning to require use of these specimens between now and early fall 2002 is urged to submit your request(s) as soon as possible. The collection's electronic database will be maintained and fully available for remote access throughout the construction period, and staff will continue to be available to answer questions and provide specific information that is not available through the department's web site <http://www.mcz.harvard.edu/Departments/Herpetology/>. For additional information, please contact Mr. José Rosado, Collections Manager: jrosado@oeb.harvard.edu.

Gopher Tortoise Council Award

Annually, the Gopher Tortoise Council awards the J. Larry Landers Student Research Award to the best student proposal submitted to the Council. Proposals can address research concerning the biology of the Gopher Tortoise, *Gopherus polyphemus*, or any other relevant aspect of upland habitat conservation. The amount of the award is variable, but has averaged $1000.00 over the last few years. The proposal should be limited to four pages and should include a description of the project, a concise budget, and a brief resumé of the student. Proposals should be submitted to: *Bob Herrington, Chair of Research Advisory Committee, Department of Biology, Georgia Southwestern State University, Americus, Georgia 31709, USA (e-mail: bherring@canes.gsw.edu).* Deadline for receipt of proposals to be considered for the 2001 award is 31 August 2001.

MEETINGS

Meetings Calendar

5–10 July 2001—American Society of Ichthyologists and Herpetologists, 81st annual meeting, Pennsylvania State University, State College, Pennsylvania, USA. Details from: www.outreach.psu.edu/c&i/ichher/.

13–17 July 2001—Societas Europaea Herpetologica 11th General Meeting, Slovenia. Details from: DPPVN/DAPTF Slovenia, Ptujska c. 91, SI-2327 Race, Slovenia; fax: +386 (0)2 788 30 51; e-mail: milan.vogrin@guest.arnes.si.

14–17 July 2001—International Herpetological Symposium 25th Annual Meeting, Detroit Zoological Institute in Detroit, Michigan, USA. Details from: www.kingsnake.com/ihs.

27–31 July 2001—44th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League (http://www.inhs.uiuc.edu/cbd/HL/HL.html). Indiana University/Purdue University, Indianopolis, Indiana, USA. Details available on page 73 of this issue of *HR* and on the SSAR web site: www.ukans.edu/~ssar/an-mtng.html.

19–23 September 2001—Association of Reptilian and Amphibian Veterinarians, Eighth Annual Conference, Orlando, Florida, USA. Details from: Charles J. Innis, VMD, VCA Westboro Animal Hospital, 155 Turnpike Road, Westboro, Massachusetts 01581, USA; tel. 508-366-1444; fax 508-634-6997; e-mail: clemmys@aol.com.

2–9 December 2001—Fourth World Congress of Herpetology, Colombo, Sri Lanka. Details from: 4WCH Promotions Office, 95 Cotta Road, Colomba 8, Sri Lanka; e-mail: admin@4wch.com; http://www.4wch.com.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres**; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Variation of Courtship Pheromones in Three Species of Plethodontid Salamanders

Male plethodontid salamanders typically transmit pheromones to females after initial courtship interactions have commenced. Previous studies suggest that courtship pheromones accelerate female receptivity to spermatophore deposition, thus decreasing potential costs of lengthy courtship rituals. Variation in the main component of the male courtship pheromones (plethodontid receptivity factor, PRF) may affect female receptivity. The authors examined variation in PRF from four allopatric populations of *Plethodon shermani*, *P. cheoah*, and *P. montanus* from North Carolina. Pheromone components were separated with reverse phase HPLC and sequenced to confirm the identity of isoforms. Relative differences were documented for PRF isoform concentrations within populations and some significant differences occurred between populations. Moreover, the presence of PRF isoforms varied between populations. The documented variation may be a result of sexual selection for isoforms that accelerate the onset of receptivity in females. It is not yet known whether female stimulation is a result of one PRF isoform or the synergistic effect of two or more isoforms.

Physiological Changes in Captured *Lepidochelys kempii* Sea Turtles

An understanding of the physiological effects of capture on sea

turtles is essential for the safe return of these endangered species to their natural habitat. Moreover, previous studies have shown that capturing turtles may affect metabolic rate, reproduction, hormone levels, and blood physiology. The authors captured individuals of *Lepidochelys kempii* near Sabine Pass, Texas with nets and took blood samples immediately after capture. Turtles were then transferred to water tanks on a boat or partially submerged cages in the water adjacent to the boat; blood samples were collected after 1 hour in each case. All turtles were then transported to a land-based holding facility where additional samples were collected for 48 hours. Mean lactate concentration was significantly higher in tank-held turtles 1 hour after capture. Both plasma NE and E levels were significantly lower in tank-held turtles 1 hour post-capture compared to initial capture values. Plasma glucose levels at 1–6 hours after capture were significantly lower than initial capture levels for cage-held turtles. No significant changes were noted for Na+ and Cl- concentrations, but K+ increased in the cage-held turtles during the first hour of capture. The authors suggested the higher K+ concentration in tank-held turtles may be a result of buffering the blood for the low pH caused by lactate accumulation.

Ecology of the Turtle *Phrynops geoffroanus* in Brazil

Recent ecological studies of turtles living in polluted ecosystems have shown that some species benefit from waste products associated with human disturbance. The authors studied a wild population of *Phrynops geoffroanus* in Brazil to determine the diet of this species, the presence of resource partitioning in regard to feeding, and any effects of anthropic influence on turtle density and biomass. Turtles were captured with fish nets and pumped for stomach contents. Morisita and Shannon-Wiener diversity indices and the "census method" were used to generate the results. Diet consisted of mainly unidentified material, although chironomid larvae and pupae, carrion, cockroaches, snails and human-associated foods such as meat and rice were also noted. Differences in the diet between adults and juveniles were noted; this finding may suggest resource partitioning in relation to feeding. The unidentified material may be organic human-associated waste that may account for the large density of turtles noted in the study.

SOUZA, F. L., AND A. S. ABE. 2000. Feeding ecology, density and biomass of the freshwater turtle, *Phrynops geoffroanus*, inhabiting a polluted urban river in south-eastern Brazil. Journal of Zoology, London 252:437–446.

Effects of Reproductive Stage and History on Call Preference in the Toad, *Alytes muletensis*

Numerous factors can affect whether female anurans will choose the same mate repeatedly. The authors tested whether repeatability would be affected by the reproductive stage or history of female midwife toads, *Alytes muletensis*. Female toads differing in the presence of eggs, development of eggs, and mating history were tested for their preference to 1.5 and 1.8 kHz male calls. Results indicated that ovulating females responded to male calls more persistently than recently-mated females. Gravid, unmated females and ovulating females preferred the 1.8 kHz call over the 1.5 kHz call; recently-mated females did not show a significant preference to either call. The results of this study differ from previous behavioral studies of leptodactylid and hylid frogs; this paradox is explained by noting the difference in reproductive biology of *Alytes*. The authors caution against interpretations based on experiments where females are tested only once.

LEA, J., T. HALLIDAY, AND M. DYSON. 2000. Reproductive stage and history affect the phonotactic preferences of female midwife toads, *Alytes muletensis*. Animal Behaviour 60:423–427.

Evolution of Caenophidian Snakes Based on Molecular Data

Caenophidian snakes currently include over 2500 species, however, very few clades within the group are well supported. Gravulund examined 12S and 16S mitochondrial ribosomal genes from 45 species of snakes in order to identify groupings within Caenophidia, assess the relationships of the problematic genera *Acrochordus* and *Dasypeltis*, test the monophyly of boigine snakes, and examine the evolution of posterior maxillary dentition and retinal visual cells within the context of the phylogeny. Genes from eighteen species of snakes were sequenced for this study; remaining sequences were obtained from GenBank and a previous study. Pairwise genetic divergences and sequence data were analyzed with PAUP 3.1.1. Because of the large size of the data set, heuristic searches were used to construct phylogenies. This analysis produced two most parsimonious trees with eight clades (1553 steps, CI = 0.313 for each tree). Results indicated that Elapidae is not monophyletic, *Acrochordus* is not a caenophidian, Boiginae is a monophyletic group, and *Dasypeltis* groups within the boigine clade. The author concluded that opistoglyph dentition arose three times in caenophidians and retinal morphology needs revision before clear conclusions can be made.

GRAVLUND, P. 2001. Radiation within the advanced snakes (Caenophidia) with special emphasis on African opistoglyph colubrids, based on mitochondrial sequence data. Biological Journal of the Linnean Society 72:99–114.

Phylogeography of the Frog *Ascaphus truei*

The tailed frog (*Ascaphus truei*) represents an ideal taxon for examining the regional phylogeography of the Pacific Northwest because it is endemic to the region, has limited dispersal abilities, and has an ancient history which may be reflected in the genetic structure of this species. Previous workers have noted differences between coastal and inland populations based on morphological and allozyme data. The authors examined sequences from 1530 nucleotides of the mitochondrial cytochrome *b* and NADH dehydrogenase subunit 2 genes from 23 populations throughout the range of this species. Data were analyzed using parsimony, maximum likelihood and nested-clade analyses. Analyses from parsimony and maximum likelihood supported the reciprocal monophyly of inland and coastal haplotypes, respectively. An analysis of molecular variance indicated that these populations have genetic structure; most of the genetic variation within these groups was partitioned among populations. The authors suggested the rise of the Cascade Mountains in the late Miocene and subsequent rainshadow effects in the Pliocene are the best explanation for the current distribution of these organisms. The authors proposed recognition of the inland population as a distinct species, *Ascaphus montanus*.

NIELSON, M., K. LOHMAN, AND J. SULLIVAN. 2001. Phylogeography of the tailed frog (*Ascaphus truei*): implications for the biogeography of the Pacific Northwest. Evolution 55:147–160.

Phylogeography of the Rat Snake, *Elaphe obsoleta*

Subspecific ranks have been used to designate isolated populations that may have the potential to evolve into distinct species. The authors examined sequences of the cytochrome *b* and mitochondrial control region 1 genes from seven subspecies of *Elaphe obsoleta*, in order to assess whether these taxa represent natural groups. Data were analyzed using maximum-parsimony and maximum-likelihood analyses in PAUP* 4.0. Results from the maximum-parsimony analysis identified three clades that are bounded by relatively major geographic landmarks: 1) an eastern clade east of the Appalachian mountains including *Elaphe o. obsoleta*, *E. o. quadrivittata*, *E. o. rossalleni*, *E. o. deckerti*, *E. o. spiloides* and *E. o. williamsi*; 2) a central clade west of the Appalachian mountains including *E. o. obsoleta*, *E. o. lindheimeri* and *E. o. spiloides*; and 3) a clade west of the Mississippi river including *E. o. lindheimeri* and *E. o. obsoleta*. The maximum-likelihood analysis produced a tree that did not show a significant difference from the maximum-parsimony analysis. When the monophyly of each subspecies was constrained, preferred results of a parsimony analysis identified 10,811 trees that were 271 steps longer than the most parsimonious trees. Intraclade comparisons of pairwise genetic distance with pairwise geographic distance did not show a clear relationship. The authors suggest small populations from each clade underwent a rapid range extension as glaciers retreated 18,000 to 6,000 years ago. The authors also suggest that subspecies based on color patterns do not represent natural groups and should be eliminated from the taxonomy of *Elaphe obsoleta*.

BURBRINK, F. T., R. LAWSON, AND J. SLOWINSKI. 2000. Mitochondrial DNA phylogeography of the polytypic North American rat snake (*Elaphe obsoleta*): a critique of the subspecies concept. Evolution 54:2107–2118.

Oil Spills and Glue: a Comment on a Sticky Sampling Problem for Lizards

MARTIN J. WHITING[1]
and
GRAHAM J. ALEXANDER[2]
[1]*Communication Biology Research Group*
[2]*Ecophysiological Studies Research Programme*
Department of Animal, Plant and Environmental Sciences
University of the Witwatersrand

e-mail (GJA): graham@gecko.biol.wits.ac.za

Recently, Vargas et al. (2000) reported results from a study comparing survivorship of lizards caught using three techniques: noosing, glue traps and rubber banding. Although their study makes valuable comment on catching lizards, the reader is imparted with a cautionary warning of high fatality rates with glue traps. We have found glue traps to be a very effective, useful and safe tool for capturing fast-moving and wary flat lizards (*Platysaurus*). We have also identified at least one flaw with the Vargas et al. study and take this opportunity to further comment on trapping lizards with glue traps.

The glue trapping technique of Vargas et al. consisted of checking traps every 15 min. In our experience, a lizard left struggling on a glue trap becomes hopelessly stuck and difficult to remove without some handling stress and/or injury. While sampling African flat lizards (*Platysaurus broadleyi* and *Platysaurus intermedius wilhelmi*), we always monitor our glue traps continuously and are usually able to remove the trapped lizard within seconds of capture. Also, in most instances, lizards were only caught by a relatively small portion of their body and therefore easily removed. This is particularly important in hot climates where lizards can quickly expire from hyperthermia on exposed traps (Bauer and Sadlier 1992).

After removing lizards from glue traps, Vargas et al. facilitated glue removal by placing the lizard in a plastic bag with several ml of canola oil (following Bauer and Sadlier 1992). Trapping and glue removal therefore constituted a single treatment and the influence of the glue cannot be separated from that of the oil in their protocol. It is possible that placing the lizard in a plastic bag with oil could contribute substantially to handling stress or that the resulting oil coating could impair physiological function. Rodda

et al. (1993) have also reported lizard fatalities from smothering, after using cooking oil in a plastic bag. Without an appropriate control in the Vargas et al. study, we cannot properly evaluate the impact of oil on lizards. In our studies, we used small amounts of cooking oil, between thumb and fore-finger, to gently massage glue from the lizard's body. If necessary, we also used paper towels to remove excess oil and glue. There was thus no need to place lizards in plastic bags and minimal oil was used. Furthermore, in instances where only a portion of the lizard contacted the trap, we did not always find it necessary to use oil.

Although many of the lizards that we captured (> 1200 *P. broadleyi*; > 40 *P i. wilhelmi*) were released the day following capture and resighted in the field as part of a mark-recapture study, we also transported *P. broadleyi* (N = 30) and *P i. wilhelmi* (N = 28) back to the laboratory for other studies and experienced no fatalities. The *P. i. wilhelmi* were used in two laboratory-based studies (McKinon and Alexander 1999; Alexander et al., in review) and released two years later, without a single fatality. Clearly, trapping these lizards with the use of glue traps had little effect on survival. Thus, although Vargas et al. are likely correct in their assertion that trap-related fatalities have a species-specific component (also see Rodda et al. 1993), we believe that their trap monitoring regime and handling procedure may also have affected their findings.

Parotoid or Parotid: On the Nomenclature of an Amphibian Skin Gland

MICHAEL J. TYLER

Most amphibians are characterized by the presence of glands dispersed throughout the dorsal skin. Frequently these glands are hypertrophied into prominent aggregations ("macrogland" *sensu* Duellman and Trueb 1985). In anurans most of these macroglands are named according to their location on the head, body, or limbs: rostral, labial, coccygeal, femoral, tibial, mental (Tyler 1987). An exception is the paired glands located upon and behind the head which are variously termed parotid, parotoid, and paratoid. Each of these names has a different meaning and it appears desirable to draw attention to the apparent confusion and suggest a means of, hopefully, achieving a standardization of terminology.

The confusion over the appropriate terminology is exemplified by a recent volume on the amphibian integument (Heatwole and Barthalmus 1994). The index in this work indicates three mentions of the term paratoid. In fact the term is used in only one chapter, whereas the other two use parotid for the same structure.

Parotid glands are large and diffuse salivary glands overlying the angle of the jaws of mammals. They are entirely subcutaneous and of ectodermal origin forming as an outgrowth of the lining of the buccal cavity (Arey 1965). There do not appear to be any homologous structures in lower vertebrates (although the structure now generally referred to as Duvernoy's gland: Taub 1967; Kochra 1978, was formerly called a parotid gland e.g., Phisalix 1922). The function of the salivary secretions is to facilitate the swallowing of food and its subsequent digestion.

In contrast the glands in amphibians often termed parotid are entirely dermal and their secretions discharge upon the outer skin. They are of ectodermal origin and have no communication with the buccal cavity; their contents have a wide range of functions but they have no involvement with digestion. It follows that the anuran structures are not homologous with mammalian parotid glands and the use of this descriptive word is inaccurate.

Definitions provided in the Oxford English Dictionary indicate that *parotis* "the parotid gland" derives from Greek *para* "beside" + *ot* -, the stem for inflected forms of *ous* "ear." *Parotid* as a noun is synonymous with *parotis* "the parotid gland"; as an adjective, meaning "situated beside or near the ear." It is applied particularly (in humans) to the largest of the salivary glands. Parotoid means "having the form, appearance, or nature of the parotid; resembling, related or allied in structure to the parotid, but not identical to it."

Here the Oxford English Dictionary refers specifically to the use of the term in anurans, stating, "applied to certain glands of the skin forming warty excrescences near the ears in some batrachians, or toads." There is no reference to paratoid.

We are aware of seven references to the use of paratoid that refer to these dorsal glands: Günther (1858), Arnold and Burton (1989), Goin et al. (1978), Lim and Lim (1992), Kennedy (1982), Ballasina (1984), Powell et al. (1998). This is not an alternative spelling of parotoid, but is appropriately applied to a different structure defined by Holmes (1979) as "a double row of poison glands extending along the back of certain amphibians, as of salamanders." Holmes states the derivation to be from the Greek word *parateinein*, "to extend along." This is the application of the word used by Francis (1934) in his classical work on salamander anatomy. The homology of these glands with anuran parotoid glands remains unproven.

Early works chiefly misidentified the nature of the glands. In one of the first classic works on frogs, Roesel von Roesenhof (1758) referred to the structures simply as "Wülste" (rolls of fat). LaCepède (1788) also failed to name them, simply describing each gland as "une éminence très-alongée, faite en forme de rein" (a very elongate protuberence in the shape of a kidney). Bonnaterre's (1789) account likewise merely noted the presence of "une excroissance en forme de rein" (an outgrowth in the shape of a kidney) behind each ear, without identifying the structure by name. According to Shaw (1802) the first identification of these dermal structures as parotoid glands was that of Schneider (1799), who included in the generic diagnosis of *Bufo* the phrase "post tympanum parotis magna poris crebris pertusa" (behind the ear a large parotid gland perforated by numerous pores). Similar terminology was used rather consistently throughout the early 19th Century, although vernacular terms were occasionally employed (e.g., Ohrendrüsen; Fitzinger 1826). Tschudi (1838), although he employed the term Parotiden himself, noted that this was not really correctly applied to these structures. Owen (1866) credited Günther (1858) with coining the term parotoid as an appropriate substitute. Although he noted that Günther's intended terminology is unclear, however; paratoid was used consistently throughout his *Catalogue of the Batrachia Salientia* (1858), but he subsequently (1860) reverted to the use of parotids in his description of a new species, *Bufo caeruleostictus*, and shortly thereafter (1864) he employed the term parotoids exclusively in *The Reptiles of British India*. Owen's preferred term, parotoid, was thereafter used in many influential works on amphibians (e.g., Boulenger 1882; Cope 1889) and has since remained the most commonly employed term.

If the meaning of the suffix -oid is assumed to be "like" or "resembling" (as used by Lynch (1971) for leptodactyloid rather than leptodactylid frogs), then parotoid is a misnomer. It does not resemble the parotid in structure, function, position, or embryological origin. It may however be the most frequently used name. To clarify this matter we examined 100 books from several hundred in our libraries. The sample included chiefly 20th century works in a variety of European languages chosen to include general herpetological works, technical morphological treatises, and a variety of regional herpetofaunas. Of those 100 volumes, 71 use parotoid.

A review of anuran references indexed in *Zoological Record* (1978–1999) and of *Biological Abstracts* (1989–1999) yields 13 references to these structures under the term parotoid, eight as parotid, and one as paratoid (Manamendra-Arachchi and Pethiyagoda 1998). An additional two references to salamander parotoid glands were also found.

Peters (1964) lists all three terms, as well as post-tympanal gland, but parotoid is presented as the primary, or preferred term. Ulber et al. (1989) reference the term Paratoide as the correct form, but note that Parotide is sometimes incorrectly applied. Kabisch (1990) admits both terms, but also gives Parotoide as the preferred form.

The English language is riddled with misnomers and it would be unwise to suggest the replacement of parotoid simply because it is inappropriate. "Dorsal cephalo-thoracic sacs" (Peneyra and Masanga 1966) is not a correct description in an anatomical sense and is unlikely to be acceptable. In summary we believe that universality is a highly desirable attribute of any descriptive word, and we propose that the term "Parotid" should be used only in reference to the salivary glands of mammals, "Paratoid" to the paired dorsal rows of glands seen in some salamanders, and "Parotoid" for the hypertrophied cutaneous glands characteristic of most bufonid and some hylid anurans.

Acknowledgments.—We thank both anonymous referees for their constructive comments.

Comments on the Taxonomy of Gopher Snakes from Baja California, México: A Reply to Rodríguez-Robles and de Jesús-Escobar

L. LEE GRISMER
Department of Biology, La Sierra University
Riverside, California 92515-8247, USA
e-mail: lgrismer@lasierra.edu

Rodríguez-Robles and de Jesús-Escobar (2000) recently published a well conceived paper on the molecular genetics of a transcontinental North American species complex within the snake genus *Pituophis*. They presented a revised taxonomy of the *Pituophis melanoleucus* complex based on mtDNA, a review of published morphological characteristics, and a distribution in which they recognize three species: *P. melanoleucus* (Eastern Pinesnakes; *P. m. melanoleucus, P. m. mugitus,* and *P. m. lodingi*), *P. ruthveni* (Louisiana Pinesnake), and *P. catenifer* (Bull and Gopher Snakes; *P. c. affinis, P. c. annectens, P. c. bimaris, P. c. catenifer, P. c. coronalis, P. c. deserticola, P. c. fuliginatus, P. c. insulanus, P. c. pumilus, P. c. sayi,* and *P. c. vertebralis*).

Rodríguez-Robles and de Jesús-Escobar (2000) demonstrated that *melanoleucus, mugitus,* and *lodingi* formed a single, well supported, diagnosable evolutionary lineage based on mtDNA characters (100% bootstrap value) and morphology (Reichling 1995). They argue further that this lineage has achieved independence from the geographically nearest lineage *ruthveni* by means of allopatry due to a broad alluvial plain laid down by the Mississippi River which currently separates the two. Based on these criteria (independence and diagnosability), they followed previous authors (e.g., Cope 1900; Fugler 1955; Klauber 1947; Wright and Wright 1957) and considered Eastern Pinesnakes to form a single species that they referred to as *P. melanoleucus.*

Using these same criteria, Rodríguez-Robles and de Jesús-Escobar (2000) elevated *ruthveni* to species status even though their mtDNA data demonstrated that it was a non-exclusive (sensu Graybeal 1995) lineage. They noted, however, that *P. ruthveni* was allopatric and morphologically diagnosable (Reichling 1995) and therefore chose to follow Reichling (1995) in maintaining its species status. They pointed out, as have others (see Graybeal and references therein), that all lineages must go through a period of non-exclusivity which simply reflects the relative recency of their divergence from their parent lineages. They appropriately noted that the diagnosability and allopatry of *P. ruthveni* demonstrated that it was an independent (i.e., reproductively isolated) evolutionary lineage.

Pituophis catenifer bimaris and *P. c. vertebralis* were considered a single species, *P. vertebralis,* by Grismer (1994, 1997). Grismer (1997) reported on the clinality of color pattern of *P. vertebralis* throughout its range (indicating that it forms a reproductively cohesive unit), and its diagnosability from (Grismer 1997:Table 1), and likely sympatry with, *P. catenifer.* In fact, these species may be sympatric for as much as 180 km (Grismer 1997). Rodríguez-Robles and de Jesús-Escobar (2000:42) implied, and Grismer (1997) demonstrated via sympatry, that *P. vertebralis* and

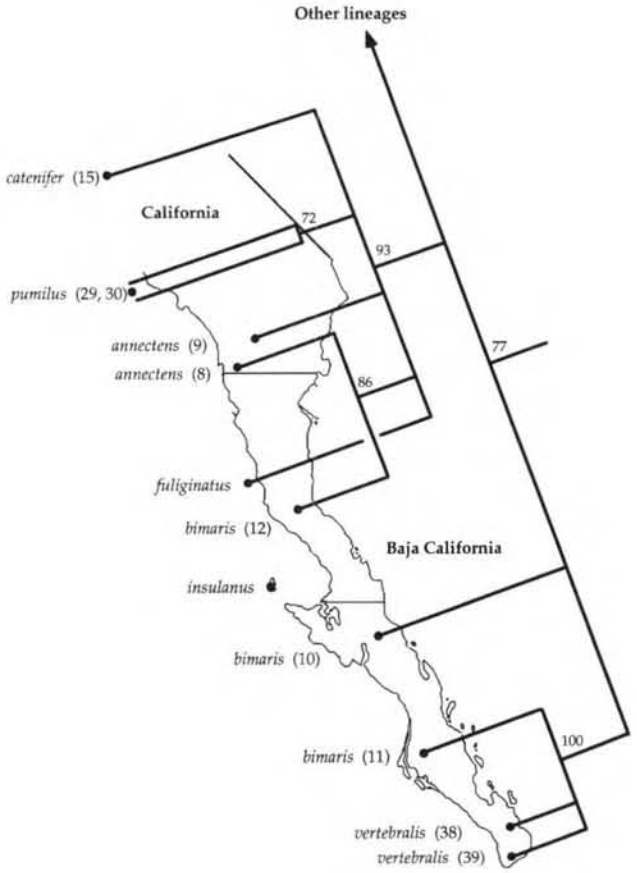

FIG. 1. An area cladogram based on a modified portion of the weighted maximum parsimony consensus tree of Rodríguez-Robles and de Jesús-Escobar (2000:FIG. 5b) containing the individuals of the Baja California gopher snake *P. vertebralis* (*bimaris* and *vertebralis*). All nodes with bootstrap values less than 70% are considered to have a probability of < 95% of being real (see Hillis and Bull 1993) and have been collapsed. All operational taxonomic units (individuals) are arranged geographically. Numbers above the nodes represent bootstrap values based on 100 pseudoreplicates each with 10 random addition iterations. Numbers in parentheses following taxon names correspond to locality data listed in Rodríguez-Robles and de Jesús-Escobar (2000: Table 1). Individuals from the pet trade (*bimaris* [13] and *vertebralis* [40]) lacking locality data could not be placed on the area cladogram and were omitted. This tree was preferred over their unweighted parsimony tree (their FIG. 5a) because the use of differential character weighting has been shown to increase phylogenetic accuracy when substitutional rate variation is present (Huelsenbeck and Hillis 1993), as suggested for these data by the maximum likelihood analysis. Their maximum likelihood tree (their FIG. 6) is similar to their weighted maximum parsimony tree except that it places *bimaris* (10) as the basal lineage in a clade containing the remaining northern lineages (*bimaris* [12] to *catenifer* [15]; FIG. 1). However, the branch length for its placement as the basal member of this clade is short, suggesting that it is weakly supported.

P. catenifer are reproductively isolated from one another (i.e., independent lineages). Rodríguez-Robles and de Jesús-Escobar (2000) synonymized *P. vertebralis* with *P. catenifer* on the basis that some individuals of *P. vertebralis* (*bimaris*) were shown to be more closely related to individuals of *P. catenifer* (*annectens*) than to other *bimaris* (Fig. 1). Their data clearly demonstrate that *P. vertebralis*, like *P. ruthveni*, is a non-exclusive lineage. When their weighted maximum parsimony consensus tree (Rodríguez-Robles and de Jesús-Escobar 2000:Fig. 5b) is redrawn with respect to geography (Fig. 1), it shows that individuals from the northern portion of the range of *bimaris* are more closely related to individuals of the southern portion of the range of *P. catenifer* (*annectens*) than they are to other more geographically distant individuals of *bimaris*. Expectedly, their tree also shows that southern *bimaris* are more closely related to the geographically more proximate *vertebralis* of the Cape Region than to the more distant individuals in the northern range of *bimaris* (Fig. 1). The substructuring of these intraspecific relationships between *P. vertebralis* and *P. catenifer* would be expected of two lineages that may have recently separated. Rodríguez-Robles and de Jesús-Escobar (2000) noted a similar relationship for individuals of *P. c. sayi* and *P. ruthveni*. Rodríguez-Robles and de Jesús-Escobar (2000) also found substantial genetic divergence (6.2%) between the *bimaris* from San Ignacio (sample 10; FIG. 1) and the *bimaris* from Ciudad Constitución (sample 11; Fig. 1). They considered this as evidence for not recognizing *P. vertebralis* (sensu Grismer 1994). However, the geographic gap between these samples in approximately 380 km and the morphology and color pattern of specimens from within this gap exhibits clinal variation, suggesting that there are no genetic breaks. The relevance of the percent sequence divergence between these two samples cannnot be fully appreciated until additional specimens from the intervening 380 km are sequenced. Therefore, using the criteria of Rodríguez-Robles and de Jesús-Escobar (2000) to recognize species level entities within the *P. melanoleucus* complex (i.e., independence and diagnosability), I elect to maintain the species level recognition of *P. vertebralis* on the grounds that it forms a diagnosable lineage that is reproductively isolated from other lineages within the *P. melanoleucus* complex.

Based on biogeography and the close relationship that other insular individuals shared with individuals from the adjacent continent, Rodríguez-Robles and de Jesús-Escobar (2000) hypothesized that *P. insulanus* (sensu Grismer 1994) of Isla de Cedros off the west coast of central Baja California (Fig. 1) should be included within *P. catenifer*. But again, using their criteria for species level recognition within *Pituophis*, I elect to maintain the species recognition of *P. insulanus* because it is a discretely diagnosable allopatric lineage (Klauber 1946). The other insular taxa—*coronalis, fuliginatus* and *pumilus*—do not meet these criteria and the first two have been synonymized with *P. catenifer* (Grismer 2001).

Acknowledgments.—I thank B. Hollingsworth, J. McGuire, J. Peters, J. Rodríguez-Robles, S. Sweet, and V. Wallach for comments on the manuscript.

Arboreal Behavior in Timber Rattlesnakes (*Crotalus horridus*)

BRAD COUPE

Department of Evolution, Ecology, and Organismal Biology
Ohio State University, 1735 Neil Avenue, Columbus, Ohio 43210, USA
e-mail: coupe.1@osu.edu

Rattlesnakes (*Crotalus* and *Sistrurus*) are typically terrestrial animals. Although many species of rattlesnakes have been observed occasionally in vegetation off the ground (Hollingsworth and Mellink 1996; Klauber 1972, pp. 486–495; Saenz et al. 1996), they are not generally recognized as proficient climbers. Klauber (1972, p. 486) noted timber rattlesnakes (*Crotalus horridus*) as being one of the more arboreal species of rattlesnakes. Here I discuss observations of arboreal behavior in timber rattlesnakes, including an instance of arboreal courtship, from a mixed hardwood forest site in Vinton County, Ohio.

During the 1994, 1995, and 1996 field seasons I radio-tracked (cf. Reinert 1992; Reinert and Cundall 1982) a total of 17 timber rattlesnakes (8 females, 9 males; Coupe 1997). I tracked three snakes (2 females, 1 male) in the late summer and fall of 1994. I tracked the two females the following summer (1995), as well as 14 additional snakes. Tracking effort was substantially reduced in the spring of 1996 as I was completing the study.

Arboreal behavior mirrored the sampling effort as none was observed in 1996, the majority in 1995, and in 1994 only one snake was observed off the ground. During the study, five of the eight females (62.5%) and two of the nine males (22.2%) were seen off the ground in vegetation in 56 of their 425 (13.2%) collective locations (Table 1). The percentage of locations in which I found these seven individuals off the ground in vegetation ranged from 1.8% to 59.5% (Table 1). I found timber rattlesnakes in arboreal locations from May to September, but most instances (35 of 56, 62.5%) were in July and August. I observed individual rattlesnakes at heights from ~ 0.5 m to ~ 5 m off of the ground.

An effort was made to locate individuals every day, but this was not always possible. Data on individuals were not collected more than once per day. Therefore, in the following discussion consecutive locations or observations are on different, but not necessarily consecutive days. Because this makes interpretation of time difficult, I have included actual calendar dates so as to clarify the time periods being discussed. When individuals were located, the species of vegetation in which the snake was found was not recorded, nor was more than a rough estimate of height noted.

Two female snakes demonstrated the greatest number of consecutive arboreal locations (= "run"). A light-phase female (LF2) was located 42 times from 5 June to 10 August 1995. On 25 (59.5%) of those locations she was observed off the ground in vegetation. A run of 21 consecutive observations of LF2 between 22 June and 16 July were arboreal (Table 1). On 29 June she reached her maximum height (~ 5 m) on the top of a broken tree trunk. The rest of the tree was still attached, but hanging down to the ground amidst lower vegetation. She had spent six days above the ground in this lower vegetation (ca. 2 m above ground level) before, presumably, crawling up the broken trunk to its highest point. She was still off the ground, but in a different location, when she was next observed on 1 July. On 13 July her eyes were cloudy. On her last consecutive arboreal location (16 July) her eyes were clearing. By 21 July she clearly had shed although her shed skin was not found. During this 21-day period of consecutive arboreal locations, she was found in three different areas of the study site that required her descent to the ground to travel between them.

After shedding, LF2 was observed off the ground on four more occasions. Most notably, at 1300 hr on 3 August 1995 she was being courted by a dark-phase male (105.8 cm SVL) that was not part of the telemetry study. They were on a steep hill, approximately two meters up in the crown of a large, fallen, dead conifer. She was stretched out on top of the branches and he was draped over her, but they were not copulating. Our presence disturbed LF2, and she moved away. This was the last time that this female was observed in an arboreal site before she was found on the ground on 10 August, dead of unknown causes.

A dark-phase female (DF1) was not located in arboreal locations when she was gravid in 1994, but in 1995 was found in elevated locations in a run of ten consecutive observations from 8 to 19 July. During this time she was located in the branches of a fallen, dead, deciduous tree. On her last arboreal location on 19 July she had cloudy eyes, and by 26 July she had shed. She was not observed in any other arboreal locations during the study.

It is possible that the arboreal behavior observed in these two females was associated with the shedding of their skin. Following long arboreal runs, both LF2 and DF1 shed their skins in the early part of the late summer mating season, a time when ecdysis has been linked to attracting mates (Brown 1995). They might have

TABLE 1. Individual snake measurements and data on arboreal behavior for seven timber rattlesnakes (*Crotalus horridus*) found off of the ground in vegetation during a field study from 1994-1996 in Vinton County, Ohio. All arboreal behavior was observed in 1995 except for observations of DM1 which occurred in 1994. A "run" is a series of consecutive observations; however, consecutive observations were not always on consecutive days (see text).

Snake	Year Radio-tagged	Sex	SVL (cm)	Mass (g)	Number of Arboreal Locations	Number of Total Locations	% of Locations Arboreal	Longest Arboreal Run
DF1	1994–95	F	90.5	385	10	137	7.3	10
DF4	1995	F	90.2	690	5	18	27.8	2
DF5	1995–96	F	89.8	725	1	57	1.8	1
LF1	1994–95	F	88.1	490	7	95	7.4	7
LF2	1995	F	80.1	605	25	42	59.5	21
DM1	1994	M	99.5	675	5	26	19.2	5
DM4	1995–96	M	112.5	1958	3	50	6.0	3
				Totals:	56	425		

been seeking better locations from which to bask in preparation for shedding, although this could in turn increase their visibility to avian predators. Two other snakes, a female (LF1) and a male (DM1) were observed in seven and five day runs, respectively, of arboreal behavior. However, they were not preparing to shed during those times. The female (LF1) did not show signs of ecdysis until 26 days after her last arboreal location, and on 24 September 1994 the male (DM1) was located in his hibernaculum immediately following his arboreal locations. More observations will be needed before a link between arboreal behavior and ecdysis can be made.

Foraging might also account for arboreal behavior in timber rattlesnakes. While I did not observe definitive arboreal foraging behavior in my study, Brown and Greenberg (1992) observed a timber rattlesnake in a vertical foraging posture on the side of a tree. This suggests a tendency to include the vertical dimension of the forest in foraging behavior, although the snake observed in this posture was a male, whereas most arboreal behavior I observed was in females. Timber rattlesnakes are well known to feed on arboreal mammals such as gray squirrels, *Sciurus carolinensis*, and chipmunks, *Tamias striatus* (Uhler et al. 1939; Smyth 1949; Savage 1967; Keenlyne 1972), and numerous species of birds have been observed in their diet (Uhler et al. 1939; Savage 1967; S. Beaupre, pers. comm.). Additionally, Savage (1967) cites Uhler et al. (1939) as including bird eggs in the diet of timber rattlesnakes; however, Uhler et al. do not make this claim. Klauber (1972 pp. 493–495) discussed a controversial painting by Audubon depicting a timber rattlesnake attacking mockingbirds (*Mimus polyglottos*) at their nest as well as an article about rattlesnakes by Audubon. While Klauber discredits many aspects of the painting and of Audubon's description of a foraging rattlesnake, he does agree that it is possible for timber rattlesnakes to feed on birds in trees.

Other researchers have noted arboreal behavior in timber rattlesnakes in different parts of their range. There is considerable variation in the frequency of observation at different sites. This variation could be an artifact of the techniques used in the study (long-term radio-telemetry studies might be more likely to observe arboreal behavior than capture-mark-recapture studies). It might also reflect population or individual level variation in the behavior. In New York, W. Brown (pers. comm.) has not observed arboreal behavior in a capture-mark-recapture study, although it has been observed rarely by E. McGowan (pers. comm.) in a radio-telemetry study. H. Reinert (pers. comm.) has frequently observed timber rattlesnakes in arboreal locations up to three meters high during his radio-telemetry studies in Pennsylvania and New Jersey. In his long-term capture-mark-recapture study, W. Martin (pers. comm.) has observed timbers in arboreal locations outside of hibernacula in West Virginia, and R. Sajdak (pers. comm.) has radio-tracked one female to multiple arboreal locations in Wisconsin. S. Beaupre (pers. comm.) has observed numerous instances of arboreal behavior in radio-tracked timber rattlesnakes in Arkansas; most of these observations were of females. While A. Savitzky and C. Petersen (pers. comm.) have observed arboreal behavior in their radio-telemetry study in Virginia, they suggest that it is rare there because these snakes might be more heavy-bodied in comparison to other populations, making climbing difficult. In North Carolina, J. Sealy (pers. comm.) has observed two radio-tracked females to remain at arboreal locations for more than a week. The behavior also has been observed in Texas (Saenz et al. 1996).

Although arboreal behavior has been reported in timber rattlesnakes (Saenz et al. 1996), I am not aware of a report of an individual timber rattlesnake spending more than half of its time in arboreal locations. Additionally, to my knowledge this is the first report of an arboreal courtship in this species. Arboreal behavior in Ohio was more prevalent in females than in males, and most locations were in or associated with fallen, dead trees or trees with branches low to the ground. Arboreal behavior might be related to skin shedding or foraging, and fallen, dead tree sites could allow for access to arboreal locations, as easily climbable branches are at ground level. These data support Klauber's (1972 p. 486) assessment of timber rattlesnakes as being "among the more persistent climbers."

Acknowledgments.—I thank B. Reisberger and V. Marshal for their help in locating snakes in the field. N. Anderson, T. Hetherington, D. Porej, W. Brown, and H. Reinert provided comments that greatly improved the manuscript. I am grateful to S. Beaupre, W. Brown, W. Martin, E. McGowan, C. Petersen, H. Reinert, R. Sajdak, A. Savitzky, and J. Sealy for sharing information on the behavior of rattlesnakes from their studies. This work was supported by grants from the OSU/Columbus Zoo joint grants program, the Nature Conservancy, the United States Forest Service, and the American Museum of Natural History. All work was performed under an endangered wild animal permit granted to me by the Ohio Department of Natural Resources. The Ohio State University Institutional Animal Care and Use Committee approved the techniques used in the laboratory.

Diet Composition of the Rainbow Whiptail, *Cnemidophorus lemniscatus* (Sauria: Teiidae), from Southern Florida

FRED PUNZO
Department of Biology, Box 5F, University of Tampa
Tampa, Florida 33606, USA
e-mail: FredPUT@aol.com

Cnemidophorus lemniscatus is a species that occurs widely in the neotropics (Cole and Dessauer 1993; Lammerée 1970; Markezich et al. 1997) and was introduced into Florida via the pet trade (Bartlett and Bartlett 1999). This species is a member of the *lemniscatus* species complex in which some species are parthenogenetic (Sites et al. 1990). Populations of *C. lemniscatus* that occur in south Florida appear to be entirely bisexual (Bartlett and Bartlett 1999). Although breeding populations have been known in Dade County, Florida for over two decades, little is known concerning the natural history and ecology of this exotic species (Wilson and Porras 1983; Markezich et al. 1997).

These whiptails are common in a number of locations in Dade County and are typically found on heavily pebbled areas of open sandy soil with scattered clumps of grasses and weeds. I have observed these lizards in the field moving quickly over the surface of the ground searching for prey, a common behavior in lizards of this genus (Vitt and Ohmart 1977; Punzo 1990). Periodically, they stop and tongue-flick at the surface of the sand before moving on. During the hottest periods of the day in summer months they frequently seek shelter in a burrow, within rock crevices, or under the shade of a plant or building.

Although it has been reported that this lizard feeds on a variety of arthropods, and less frequently on the flowers of some plants (Sites et al. 1990; Bartlett and Bartlett 1999), no detailed studies have been conducted on the diet composition of this species in Florida. The purpose of the present study was to analyze the stomach contents of *C. lemniscatus*.

Materials and Methods.—The study site was located 1.2 km southeast of the former Florida East Coast Railway Building (N.W. 37th Ave. and 75th St.) (Miami, Dade Co., Florida, USA) in an area adjacent to several occupied and abandoned buildings. The area included an asphalt parking lot overgrown with weeds adjacent to a well-drained and an open sandy area sparsely vegetated with grasses (*Andropogon* spp., *Aristida stricta*), saw palmetto (*Serenoa repens*), and composites (*Aster* spp.). This sandy area was bordered on two sides by a large area characterized by clumped shrubs and an open woodlot. The lizards often entered this area to forage and seek shelter from the sun.

All lizards were collected from 7 March to 30 August 1999 by noosing as described by Fitch (1958). Only the stomach contents from adult lizards were used in this study (snout–vent length [SVL] = 100–123 mm). Following capture, lizards were measured (SVL, to the nearest 0.1 mm) with vernier calipers, weighed (to the nearest 0.01g) on an Ohaus Model 31677 Port-O-Gram electronic balance, and sexed. Stomach contents were collected using the stomach-flushing technique described by James (1990) and Punzo (2001). Lizards were given individual identification marks by toe clipping for future demographic studies and then released at their original collection site. The stomach contents for each lizard were placed in a plastic vial containing 70% ethanol and returned to the laboratory for subsequent identification. Only lizards captured for the first time were used for stomach analyses (N = 30; 16 males, 14 females). Prey items were identified to Order and Family wherever possible.

For each prey item, length (a) and width (b) were measured to the nearest 0.01 mm (excluding legs and antennae) and volume was determined according to the formula for the volume (V) of a prolate spheroid (Dunham 1983; Punzo 1991, 2000; Vitt and Breitenbach 1993): $V = 4/3p\ (a/2)(b/2)^2$.

Results and Discussion.—Adult males exhibited a SVL ranging from 60 to 100 mm, and females ranged from 70 to 105 mm.

Body mass ranged from 16.3 to 19.8 g in males, and 15.4 to 20.7 g in females. In my laboratory I have observed captive females laying 1–2 clutches of eggs per reproductive season, with clutch sizes ranging from 2 to 5 eggs (unpubl. data). Embryonic development is completed after 45–52 days of incubation under controlled conditions (27°C, 75% RH, 14L:10D photoperiod) (unpubl. data).

Prey items (number of prey, percent of total sample, percent volume, and percent frequency) found in the stomachs of *C. lemniscatus* are shown in Table 1. There were no significant differences between sexes (c^2, $p > 0.03$) or between the months during which sampling was conducted (Two Sample Means Test, assuming unequal variance, $p > 0.10$; Sokal and Rohlf 1995).

These lizards are active foragers and consumed a wide variety of arthropod prey suggesting that they are opportunistic predators. Similar results have been reported for other species of *Cnemidophorus* (Best and Polechla 1983; Maya 1989; Paulissen and Walker 1994; Punzo 1990; Smith 1989). Orthopterans and beetles were the most common prey items found in lizards at this study site, together representing 56.9% of the total number of prey items consumed and 71.2% of the total volume of prey consumed. Although ants and termites occurred in 23.3% and 26.6% of the stomachs, respectively, they accounted for a relatively small percentage of the diet by volume. Spiders and lepidopteran larvae are readily consumed by *C. lemniscatus* as well. These lizards are also capable of detecting beetle larvae that are below the ground surface, as well as termites. This has been reported for other species of *Cnemidophorus* (Fitch 1958; Mitchell 1979; Punzo 1990) as well as for other genera within this family (Cooper 1990). Arthropods with well-known chemical defenses such as blister beetles (Meloidae), velvet ants (Mutillidae), and millipedes, which were common at this study site, were not present in any of the stomachs examined.

An insular species within the *lemniscatus* species group (*C. arubensis* from Aruba) was strongly herbivorous (Schall and Ressel 1991), with flowers, fruits, and leaves comprising 80–90% of the diet. This whiptail appeared to actively search for certain (preferred) food types and actively avoided plants that contained large quantities of phenolics, saponin, or alkaloids. Paulissen and Walker (1994) showed that another insular species, *C. nigricolor,* consumed some plant material but not enough to be considered an herbivore.

In summary, *C. lemniscatus* in southern Florida feeds primarily on orthopterans and coleopterans, followed by lepidopteran larvae and spiders. There was little evidence that this whiptail feeds on plant material at this study site. Studies on *C. lemniscatus* from South America indicated that these lizards feed on a wide variety of arthropod prey, including termites, beetles, grasshoppers, katydids, and spiders (Markezich et al. 1997). Although termites comprised only a small percentage by volume of the diet of *C. lemniscatus* from southern Florida, isopterans can account for a larger proportion of the diet (> 10%) in individuals from South America.

TABLE 1. Analysis of stomach-flush samples from *Cnemidophorus lemniscatus* in Florida. A total of 30 stomach samples from different adult lizards were analyzed, all containing food. The results are expressed as the total number of prey items (N) for each taxon for the 30 lizards, the percent that N represents of the total sample of dietary items (percent total number), percent for each taxon by volume, and percent frequency (percent of lizard stomachs containing a particular prey item).

The Jalisco Mud Turtle, *Kinosternon chimalhuaca*, in Northern Nayarit, Mexico

ROBERT G. WEBB

Laboratory for Environmental Biology, and Department of Biological Sciences
University of Texas at El Paso, El Paso, Texas 79968-0519, USA
e-mail: rgwebb@utep.edu

For many years a kinosternid turtle has languished unidentified in the herpetological resource collection of The University of Texas at El Paso (UTEP). The specimen was obtained during field activities of a seven-man crew that visited several sites in northern Mexico in the summer of 1962 (trip alluded to by Milstead and Tinkle 1967).

Around noon on 23 August 1962 we checked into the Hotel Plaza, Acaponeta, Nayarit. Crew members (except Milstead [sick in bed] and Webb [curating backlog of specimens]) left Acaponeta at 1330 h and traveled south on Highway 15, returning at 1830 h. The prime objective, to obtain topotypic *Terrapene nelsoni,* was unsuccessful, but the trip culminated in the capture of three hand-collected kinosternid turtles given to me by D. Tinkle. The three *Kinosternon* included two *K. integrum* (UTEP 3906–07) and the unidentified *Kinosternon* (UTEP 3908). The locality for the three UTEP turtles was recorded as 6.8 mi (11 km) south of Acaponeta, which is about 217 air km north of the northernmost locality of *K. chimalhuaca* (21 km S Puerto Vallarta; Berry et al. 1997:334, 336). The capture site as described by the collectors was along Highway 15 at a roadside flooded grassy area said to have aquatic vegetation, suggesting a permanent pond (but may have been seasonal depending on rainfall). The quiet-water pond site is concordant with the preferred habitat of *K. chimalhuaca*. In this article I tentatively assign this specimen to *Kinosternon chimalhuaca* (Berry et al. 1997; reviewed in Iverson and Berry 1998). However, some morphological differences between UTEP 3908 and those of *K. chimalhuaca*, perhaps significant, exist (see below).

The northern Nayarit *Kinosternon* (UTEP 3908) is a juvenile female (based on short, small tail) with maximal straight-line measurements (Vernier calipers) of 87.3 mm (carapace length, CL), 63.7 mm (carapace width, CW, juncture second and third costals), 70.2 mm (plastron length), and 22.6 mm head width. The carapace is widest posteriorly and shows no carination. The anterior vertebral scute is narrow, well separated from contacting the second marginal scutes. The tenth marginal is slightly higher than the ninth and eleventh marginals. Character codes relating to plastral features used by Berry et al. (1997) are AHW 38.4 mm, BRL 11.0 mm, FEL 11.2 mm, HL 31.4 mm, and PHW 30.8 mm; values for two of their derived ratios, PHW/CW 0.48 and BRL/CL 0.13 (Berry et al. 1997), are extreme, suggesting a narrower posterior lobe of the plastron and narrower bridge in UTEP 3908. The head width/CL of 25.9% also suggests a wider head (Berry et al. 1997). The axillary and inguinal scutes are in broad contact (both sides), but their compactness and reduced contact with marginals seems significant compared to UTEP 3917–18, 3900 (= *K. chimalhuaca*, cited in Berry et al. 1997); the axillary contacts most of the fifth marginal/anterior part of sixth, the inguinal most of the sixth/anterior part of the seventh marginal. There is no anal notch.

The overall dorsal coloration (in life, Webb field notes) of the soft body parts was grayish, but finely marked with buff or yellow-orange. This same pattern occurred on top of the head with more yellow-orange (brighter pattern) on the side of the head (similar to pattern of turtle depicted in Berry et al. 1997). The chin (with one pair of smallish barbels), throat, and soft body parts in the inguinal regions were pale yellow, and the underside of the neck whitish. The ventral soft body parts were mostly flecked with gray. The carapace was dark olive; the bridges, edges of marginals, and plastron were orange-brown.

The most notable differences from the description of southern *K. chimalhuaca* are the much smaller plastron, narrower width of posterior plastral lobe at posterior hinge (PHW), narrower bridge (BRL), configuration of the axillary and inguinal scutes, and the absence of an anal notch. Some differences of UTEP 3908 may reflect juvenile rather than adult features (smallest mature female 99 mm CL; Berry et al. 1997). The possible geographic consistency of these features of a population in northern Nayarit remains to be determined. The coastal lowland habitat and north-south continuity of *K. chimalhuaca* may be interrupted by the elevated western extent of the Transverse Volcanic Range (Neovolcanic Plateau) that is abruptly precipitous to sea level in the Tepic area of Nayarit.

Acknowledgments —For field companionship I thank Walter Auffenberg, his son Walt Jr., Donald Tinkle, Louis Irwin, William Milstead, and Donald Patten. The 1962 trip was funded by NSF grant G2302 (to Milstead).

Silent Auction Returns to Indianapolis

The SSAR Silent Auction will be held again this summer at the annual meeting of SSAR/HL in Indianapolis. Throughout the meeting, herpetology-related artwork will be on display in a central location so that everyone in attendance will have an opportunity to bid on each piece. At the end of the meeting, each piece will be sold to the highest bidder. Funds generated from the Silent Auction are used for SSAR Student Travel Awards. Therefore, SSAR student members need your help! You are invited to donate a print, photograph, line drawing, plate, engraving, or other frameable artwork to the auction. Last year, over $2000 was raised by the Silent Auction to defray travel costs for graduate students presenting papers or posters at the annual meeting. We would like to uphold or surpass the efforts of previous years so that more graduate students may be able to participate in our annual meeting. All donations are tax deductible (for U.S. residents) and more importantly, will provide a financial boost to rising herpetologists. To donate an item or for more information, please contact: *Scott Boback, 331 Funchess Hall, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849-5414, USA; e-mail: bobacsm@auburn.edu.*

Teflon Tubing as Radio Transmitter Belt Material for Northern Leopard Frogs (*Rana pipiens*)

HEATHER L. WAYE
Department of Zoology, 3029 Cordley Hall
Oregon State University, Corvallis, Oregon 97331, USA
e-mail: wayeh@bcc.orst.edu

Techniques for securing radio transmitters to anurans have included the use of belts made of polyethylene tubing (Bartelt and Peterson 2000) or of beaded chain (Rathbun and Murphey 1996). Both of these designs have been used with success, but also have resulted in some incidence of injury and entanglement of the study animals. Here I present a new material for radio transmitter belts that is potentially less injurious to frogs.

Teflon tubing (TT250/22-25-GRN, Manhattan/CDT/Cole-Flex and Thin Wall Teflon Tubing, Alpha TFT 200 22 NAT) was used to attach radios to *Rana pipiens* at the Creston Valley Wildlife Management Area, near Creston, British Columbia, Canada, in 1998 and 1999. The radios were made by Holohil Systems Ltd. (112 John Cavanagh Road, Carp, Ontario, K0A 1L0, Canada), models BD-2G (1.8 and 3.5 g) and BD-2 (1.3 and 1.0 g), and by AVM Instrument Co. Ltd. (2356 Research Drive, Livermore, California 94550, USA), model SM1 (2 g). Radios were less than 7% of the frog's weight and were built to operate for 9–26 weeks. The tubing was fitted to the frogs such that the loop slid snugly over the adpressed thighs, and was tied using cotton thread pulled through the tubing. Cotton thread should allow unrecovered radios to fall off the frogs when the thread rots and breaks. The frogs were generally caught on shore close to water, in moderately thick reed canary-grass habitat. The pattern of spots on the dorsal surface of the frog was photographed and sketched for later identification.

The effectiveness of Teflon tubing radio transmitter belts was examined with a total of 24 frogs in the field. In 1998, I placed radio transmitters on 13 male frogs, from 23 September to 30 October. There were 189 frog-days of telemetry, with 110 observations of frog locations. In 1999, three males were fitted with radios in June and eight females in September. There were 23 frog-days of telemetry in the summer (10 observations) and 123 frog-days in the fall (to 31 October, 50 observations). To monitor the effects of the belts, frogs were recaptured about every 10 days and their condition recorded.

Most of the frogs did not move more than 100 m during the period they were monitored, and by the end of October all were found along the edges of deeper water bodies. Three radioed frogs went underground into small mammal burrows near the water's edge, and apparently spent the winter there; the belts did not seem to limit the mobility of these frogs. Although there was no evidence that the belts significantly restricted the movements of the frogs, on two occasions I observed a frog trying to back into vegetation under water, and this movement was briefly impaired by the radio unit.

TABLE 1. Comparison of numbers of injuries, deaths, and shed belts between radio telemetry belts made from Teflon tubing and from beaded chain. R&M = Rathbun and Murphey (1996).

Source	No. frogs	No. injuries	No. deaths	No. escapes
R&M	55	6	5	12 (to 22)
This study	24	1*	1*	15

*same frog

Out of 24 frogs fitted with radios, six frogs were refitted to better adjust belt sizing, and 15 resulted in the frog eventually slipping out of the belt. Five of these frogs slipped their belts within 24 hours; three of these were in the first two days of the study, when I was experimenting with the fit of the belt. The average time for belt loss in 1998 was 2.7 days (range 1–11 days) and in 1999 was 9.0 days (range 1–20 days). One male fitted in October 1998 was recovered the following spring without the belt; presumably either the thread had rotted away or the frog had lost enough weight over the winter to slip out of the belt. The maximum length of time a frog carried a belt is unknown, but one belt remained on one frog for over four months.

When I checked the frogs for the fit of their belts, I occasionally saw marks on the skin, especially across the dorso-lateral folds, but these did not deepen to become open wounds. Nine of the 10 frogs examined appeared uninjured. Six had indentations across the dorso-lateral folds, and three had no marks. These indents appeared approximately 12 days after the belt was fitted. One frog sustained deep cuts on its sides from the belt and later died. The frog that was recaptured the following spring without its belt did not have any scars or wounds. There was no evidence that any frog had become entangled in vegetation, and shed skin did not become caught up on the belt.

Rathbun and Murphey (1996) reported the number of radios that were shed by frogs and the number of injuries due to belts made of beaded chain; their data are presented in comparison to the results of this study below (Table 1). I had proportionately more escapes overall (20% of these occurred in the first two days of the project), but fewer injuries and deaths due to the belts. The Teflon tubing was stiffer than polyethylene tubing and tended to stick out from the body of the frog. This might make it more likely to catch on vegetation, but might also make it easier for the frog to slip out of the belt if it becomes entangled. The stiffness of the tubing belt also meant that it touched the skin of the frog at fewer points, and the slick surface of the Teflon seemed to minimize abrasion. Teflon tubing belt material appears to be a suitable material for the attachment of radio transmitters to anurans.

Acknowledgments.—I thank the Columbia Basin Fish and Wildlife Compensation Program for funding this project; Manning, Cooper and Associates for giving me the opportunity to work on this project; and the Creston Valley Wildlife Management Area for their support. I would also like to thank Dede Olson for her extremely helpful editorial comments. This work was done under permit from the B.C. Ministry of Environment, Lands and Parks.

A Technique for Detecting Eyeshine of Amphibians and Reptiles

Spotlighting has been a standard technique for locating amphibians and reptiles at night. The basic technique is to shine a flashlight at an animal so that the light reflects off of the animal's retina, creating a noticeable eyeshine. The method works well for species with larger eyes such as alligators and ranid frogs, but is fairly ineffective for detecting most medium- and small-sized animals because their eyeshine doesn't stand out sufficiently from the background. A brighter light is of little benefit, because it does not enhance the contrast of a weak eyeshine against the background, and the light is much more likely to cause animals to flee, turn away, or simply close their eyes.

We have used a modification of the basic eyeshine technique so that it allows us to detect animals at a much greater distance and to detect much smaller species. We use binoculars in combination with a moderately bright light. We rest the binoculars on the top of a light, line up the field of view with the light beam, and then move the two in unison while scanning for eyeshine. It generally takes a few hours of practice to effectively coordinate the light and the binoculars, but once mastered, the technique becomes easy to use and greatly enhances an observer's ability to locate animals. We have not quantified the effectiveness of using binoculars while spotlighting, but we estimate that it increases the number of individuals located by two to five fold, with the greatest increase being the more cryptic and smaller species.

Almost any set of binoculars can be used, but some are more versatile. Binoculars that can focus to within < 2.5 m are particularly useful because this allows one to locate nearby animals. The 7 x 26 Bausch & Lomb Custom binoculars and the waterproof Bausch & Lomb Elite 10 x 42 work well.

The choice of light is important for getting the best results. If the light isn't sufficiently bright, it can be difficult to distinguish vertebrate eyeshine from other reflections, especially water droplets. Ambient light has a profound effect. On a dark night, even a low powered flashlight can be used to good effect, whereas bright moonlight will limit the range of even a fairly intense light. If the target animals are only visible over a short range, as when search-

ing in fairly dense vegetation, a light of lower intensity is often advantageous, because it doesn't dazzle your eyes and will be less likely to disturb the subject. If the target animals are likely to be seen at substantial distances, then a brighter light works best. Atmospheric conditions, such as dust in the air or rain, will often limit the effective range. For most purposes, a light of intermediate intensity is a good choice, and a 30-watt spotlight is a good compromise. Table 1 provides a comparison of light output from various lights and Table 2 provides reference data for environmental light conditions that *Rana aurora* might be exposed to when sitting near a pond during the day.

A light should ideally have a beam angle a little greater than the field of view of the binoculars being used. A light that produces even illumination is best.

Just as important are factors that affect comfort. If the light is too heavy, it can quickly become tedious trying to hold it with the binoculars perched on top, and maneuverability will be compromised. Most importantly, it should be easy to hold the binoculars in place on top of the light because the binoculars need to be as close as possible to the beam of light.

One commercially available light that works well is the Nite Sport II (Nite Light, Little Rock, Arkansas, USA, US $70). This light has a rechargeable 6 volt gel cell battery (that can attach to one's belt) and a headlamp unit. The 1.3 m cord connecting the battery to the headlamp is particularly sturdy, so it is not the weak point as it is in many headlamp systems. The light runs about 5 hours on a charge. The optional Halogen bulb (HMP03) increases the light output from 67 to 79 lux (measured at 5 m). A particularly nice feature of the Night Sport II is the built-in rheostat. This allows one to use the full power of the light to locate animals, but then reduce the brightness for the final approach.

We have modified our lights by bolting a Mag-Lite Bite-a-Lite (Mag Instrument, Ontario, California, USA, www.maglite.com) to the clip on the back of the headlamp. Bite-a-Lite is a small plastic part that fits over the end of a AA Mag-Lite so you can hold it in your teeth. By drilling a 3 mm hole through the Bite-a-Lite, a 3.5 cm long bolt and washer can be used to attach the Bite-a-Lite to the Nite Sport. This modification makes the light easy to hold and frees one's hands.

Alternatively, you can assemble a 30-watt light from readily available parts. Night Lite sells a spotlight (W1585) that can be modified by upgrading their 6-volt bulb with a 12-volt H4405 sealed beam lamp (Bulbman, tel. 1-800-648-1163, www.bulbman.com) that produces 1468 lux (at 5 m). You will then need a 12-volt gel cell, charger, and a connector for the light and battery. These parts are available at many electronic stores.

In many situations, vegetation blocks the eyeshine of a particular animal from all but a few viewpoints. This makes it difficult to point out an animal to anyone else or, sometimes, even to keep track of where an animal is as you approach it. We have found that it is often helpful to work in pairs with one person spotting animals and the other doing most of the capturing. In this situation, a laser pointer can be a useful accessory. When an animal is located, a laser pointer can be used to direct a second person's attention to the animal. It is generally not a good idea to place the laser spot right on the animal since the bright light can elicit an escape response. The pointer can be used instead to "draw" a small circle around the animal. A second method is to illuminate a spot about 1 m away from the animal and then move the beam towards it, turning the pointer off just as the spot reaches the animal. Note that lasers come with a range of ratings for light output. The more powerful ones (which claim to reach > 200 m) are generally the most useful. Shorter wavelengths provide better visibility, so a 635 nm laser appears nearly seven times brighter than a 670 nm unit with the same output.

There are a few precautions to keep in mind when spotlighting. When working with a partner to catch more wary species, it is important to make sure that the person approaching an animal is not illuminated from behind since this creates a strong silhouette that immediately alerts the animal to the approaching biologist. Similar precautions are necessary when working under a full moon.

Vertebrates are not the only animals with eyeshine. Spiders have surprisingly bright eyeshine and tend to be very abundant, but their eyes look more point-like than those of vertebrates. Moth eyes and small droplets of pine sap can look extremely similar to vertebrates' eyes. Water droplets become abundant when the temperature drops to the dewpoint, and while water droplets generally are not too difficult to distinguish from vertebrates' eyes, their sheer abundance can be very distracting.

Spotlighting has been used primarily for anuran surveys, but

TABLE 1. Light output measured in lux (=lumens/m^2) at a standardized distance of 5.0 m using a digital light meter (Model 407026, Extech Instruments, Waltham, Massachusetts, USA; www.extech.com).

Light Source	Lux
Q Beam - 200,000 cp	786
100 Watt - sealed beam	653
Q Beam - 100,000 cp	558
30 Watt - sealed beam	358
35 Watt - garden flood	70
Mag-Lite - 3 D-size cells	39
Nite Sport II - Halogen bulb	18
Nite Sport II - Regular bulb	16
Mag-Lite - 2 AA-size cells	1

TABLE 2. Mid-day ambient light levels measured at a *Rana aurora* breeding pond at Point Reyes National Seashore, California. Measurements were taken at eight places where frogs had been observed sitting during the day on previous occasions. The light meter sensor was oriented at three different angles and the range of values is reported for the eight sites.

Light Source	Lux
Full sun	100,000
Full moon	2
Partially shaded pond edge	
Facing toward sun	40,000–80,000
Facing north	7,000–10,500
Facing south	12,500–25,000

the technique is far more broadly applicable. For example, it is particularly effective for terrestrial salamanders, even in areas with moderately dense understory. We regularly spotlight even the more diminutive species such as *Batrachoseps attenuatus*, *Plethodon elongatus*, and *Rhyacotriton variegatus*. In less than one hour (on a rainless night), we were able to spotlight five adult *Dicamptodon tenebrosus* away from water; this is especially notable since this species is generally difficult to find during the day without moving significant amounts of cover. Spotlighting is useful for reptiles as well. One of the authors (CC) originally used the technique in Australia for locating nocturnal geckos, snakes, frogs, and small mammals.

We have found that many species of salamanders in the western U.S. can be found during remarkably dry weather. In such conditions, most animals are found sitting near the entrance to a small burrow or within a crevice, but there are typically a few individuals that are out well away from cover. Spotlighting with binoculars should be considered when looking for amphibians and reptiles in habitats that are easily impacted by more traditional collecting techniques (e.g., moss-covered talus slopes), where it is difficult to turn cover (e.g., searching for geckos on lava flows or on the trunks of trees), or where repeated surveys are necessary and other techniques (e.g., time constrained surveys) would result in unacceptable levels of habitat disturbance.

With an increasing interest in survey techniques, especially for declining amphibians, biologists should include spotlighting with binoculars as one of their tools. It is an efficient technique that is easy to learn and that uses equipment most biologists already possess.

Evaluating Visual Implant Elastomer Polymer for Marking Small, Stream-dwelling Salamanders

MISTY-ANNE RALSTON MAROLD

e-mail: Mralston@forwild.umass.edu

Traditionally, amphibian mark-recapture studies have relied on toe clipping. Although effective for seasonal studies of adults, larval amphibians can regenerate toes quickly, making this technique unsuitable for longer-term studies. Several alternative amphibian marking techniques were reviewed recently by Schlaepfer (1998) and Nauwelaerts et al. (2000). However, the majority of alternative techniques (PIT tags, pressurized fluorescent marking, coded wire tags) may be unsuitable for small larval and adult salamanders. I tested the suitability of Visible Implant Fluorescent Elastomer (VIE) tags on larval and adult *Eurycea bislineata* and *Desmognathus fuscus* (Plethodontidae). As larvae, they are slender bodied, stream forms, and range from 14 to 34 mm snout-to-vent length (SVL) and 1.9 to 3.0 mm head width. These species lack the large fin-fold, common with pond breeding salamanders.

Laboratory Study.—A laboratory study was conducted on 27 larval (18.1–28.4 mm SVL) and 2 adult (26.5 and 27.1 mm SVL) *Eurycea bislineata*. I randomly selected 27 larvae and both adults for marking. They were individually anesthetized with MS-222 (400 mg/L, 1:2500) buffered with equal parts sodium bicarbonate (E. L. Brainerd, pers comm). I identified five potential mark locations on each side of the body (anterior and posterior to foreleg, midbody, and anterior and posterior to hindleg) and four dorsal positions (posterior to leg attachments on dorsal side) for a total of 14 potential mark locations. I tested 1 to 4 marks per individual (8 larvae, 1 mark; 12, 2; 4, 3; 3, 4). To minimize desiccation, salamanders were placed on a water-soaked artificial chamois for the duration of the procedure. I used methods similar to Nauwelaerts et al. (2000) to inject a small dot/line of elastomer under 10x magnification. Although marks were pliable when dried, I avoided placing them near joints to minimize potential mobility impairment. After marking, the salamander was allowed to recover in clean stream water, then returned to an environmental chamber maintained at 12.7 ± 0.5°C. VIE marks were checked each week for 15 weeks by placing the salamander into a ziploc bag and viewing the mark with a 10x magnifying lens. Within the containers, I observed swimming and walking ability to determine if mobility was impaired.

Eurycea bislineata larvae and adults tolerated the tagging procedure with no mortality, limb-loss, or obvious injury. There was complete retention of the VIE marks for 15 weeks in the laboratory. Overall visibility of the marks varied due to skin pigmentation and placement of the VIE. VIE marks in mid-body positions were more difficult to insert and could be confused with adjacent marks; therefore, I decided these were unsuitable. Further, larvae <19.0 snout-to-vent length were too difficult to mark due to their small size relative to the needle.

Field Application.—I utilized the VIE marking technique in a field test from May to September of 1998. Using the 10 body positions identified from the laboratory study, I administered four marks per individual. I captured 132 salamanders, of which only 44 were >19 mm SVL (*Desmognathus fuscus* 1 adult, 15 larvae; *Eurycea bislineata* 3 adults, 25 larvae). Individuals were anesthetized with MS-222, rinsed, placed onto a wet chamois-covered sponge, and marked under 10X magnification. After marking, they were placed into a bucket of clean stream water for recovery and then returned to their capture location. None of the 44 marked individuals was recaptured during the three months of fieldwork, but I attributed this to marking only a relatively small portion of a functionally open population.

Conclusions.—The VIE technique was successfully utilized for *Eurycea bislineata* (lab and field) and *Desmognathus fuscus* (field) ranging from 19.0 mm to 41.1 mm SVL. The elastomer was relatively easy to see under the skin, although a blue light was necessary for darker-pigmented individuals. It only took about 30 s to inject the four marks in the field. The nature of my study was such that I was repeatedly collecting, marking, and replacing individuals over 500 m of a stream. Therefore, I had to mix a batch of elastomer, mark some individuals, then move on. The relatively high air temperatures (27–32°C), tiny quantity injected, and time between marking allowed the elastomer to harden before I actually used it all. I typically had to mix two batches per 10-h field day, despite keeping the material on ice. Each batch of elastomer cost about US $11.00 plus the cost of the handheld injector, blue filtered light, and amber glasses. On average, I used 10 batches of

elastomer a week for three months, which added substantially to material costs for the project. The entire procedure (anesthetization, marking, recovery) took about 20 min per individual, which limited the number of collection sites I could visit each day and return individuals to their capture location. I found the VIE technique to be more appropriate for situations where marking a large number of individuals at once was possible (e.g., laboratories, small closed water-bodies, during mass migration, or other area/time constrained studies). This study suggests that VIE may be a suitable alternative to toe-clipping for small adult and larval salamanders, but is limited by long handling time per individual and increased costs.

Acknowledgments.—This project was funded by the Massachusetts Division of Fisheries & Wildlife and the Cooperative State Research, Extension, Education Service, U.S. Department of Agriculture, Massachusetts Agricultural Experiment Station, under Project No. MAS 00080. C. Griffin and A. Marold provided editorial advice. A. Richmond and E. Brainerd provided anesthesia guidance. C. Baumann and B. Bayne assisted with animal care, marking, and field applications. Northwest Marine Technology, Olympia, Washington provided technical advice during the project. The University of Massachusetts Institutional Animal Care and Use Committee approved the methods used in this project.

Longevity of Paint Marks and the Lack of Effect on Survivorship and Growth of *Sceloporus* Lizards

The most appropriate and useful techniques for marking free-ranging individuals are those that are long-lasting relative to the duration of the study and have little effect on survival or growth (Jones and Ferguson 1980). Recently, Boone and Larue (1999) reported that side-blotched lizards (*Uta stansburiana*) experienced a dose-related decline in survivorship due to xylene-based paint. Because we use paint marking in our research on lizards, we were concerned whether these results applied to other species.

We repeated aspects of the Boone-Larue experiment using two species of *Sceloporus* but modified several aspects of the protocol. We conducted our experiment during the reproductive season (late May to late June) of these species. We also used a less frequent handling and marking regime (described below). Finally, we measured survivorship of the two species, but each species was marked with a different type of paint. *Sceloporus virgatus* was marked with xylene-based paint, and *S. undulatus consobrinus* was marked with latex-based paint.

Xylene-based paint experiment.—We noosed 23 lizards (11 females, snout-vent length, SVL 40–53 mm; 12 males SVL 44–57 mm) from the Chiricahua Mountains, near the Southwestern Research Station of the American Museum of Natural History, (Portal, Arizona, USA), on 17–21 May 1999. Lizards were housed in the laboratory for two days prior to marking to ensure that no animals died after capture. On the third day, the SVL of each individual was measured to the nearest mm with a transparent ruler, and the mass of each lizard was measured to the nearest gram with a Pesola spring scale. Like Boone and Larue (1999), we used adult animals spanning a range of body sizes. Thus, if there were any dose-related responses, smaller individuals should have been the first to be affected.

We painted six males and six females with a 2 x 12 mm line of green Faber Casteel™ xylene-based paint on the dorsum. We handled the other 11 lizards (six males and five females) in a similar manner and we applied a stripe of water to the dorsum as a control. All *S. virgatus* were maintained in a single large outdoor enclosure (3 x 6 m), until 18 June 1999 and then moved (coinciding with a day seven measurement; see below) to another outdoor enclosure (2 x 1 m). While in both enclosures, lizards were provided with refugia (rocks piles and leaf litter), crickets, and water ad libitum. We re-captured all lizards weekly for four weeks to measure SVL and to check if paint needed to be re-applied.

Four *S. virgatus* (three males and one female) died during the xylene experiment, including one painted male lizard (47 mm) and three control lizards (43, 47, and 50 mm). There was no difference in survivorship between painted and control lizards (χ^2 = 1.011, df = 1, $P > 0.05$). The mean SVL of lizards that died (46 mm) and that survived (50 mm) also did not differ ($t = 0.111$, df = 21, $P > 0.05$). Among the surviving painted and control lizards, growth ($t = 0.486$, df = 21, $P > 0.05$) and mass ($t = 0.759$, df = 21, $P > 0.05$) also did not differ. Except for two individuals, the paint remained on the dorsum of lizards for the four-week study. Paint was re-applied to two individuals, one at the first week and the other at the fourth week. Boone and Larue (1999) reported that application of paint appeared to cause discomfort (i.e., gaping and dorsal-ventral flattening). We did not observe any behavioral differences after applying the xylene-based paint.

Latex-based paint experiment.—For the latex-based paint study we captured 9 males (SVL 52–65 mm) adjacent to the Cave Creek Wash, east of the Foothills Road, in Portal, Arizona, on 7–17 June, 1999. Lizards were housed in aquaria for two weeks prior to marking. We painted all lizards with two abdominal patches (1 x 4 cm) of "blue" or "snow white" latex paint (Tulip Pearl Fabric Paint, Tulip, Clovis, California, USA), and one dot (ca. 1 cm diam) of "snow white" paint on the head or the base of the tail of each male. The males were used in a behavioral study lasting approximately 24 h, and maintained individually in terraria for four weeks.

While in the terraria, lizards were provided with crickets and water ad libitum, and dirt substrate with pieces of bark for perches. No lizards died and the paint remained on the both the dorsal and ventral surfaces of all lizards during the four-week period. Thus, this latex paint when applied over a relatively large proportion of the ventral surface (ca. 80%) had no measurable effect on survivorship of captive male *S. undulatus consobrinus*. Furthermore, the latex paint persisted for at least four weeks on lizards housed with soil and tree bark substrata, which approximated the natural substrates of this species.

Our data show that both xylene- and latex-based paints show no measurable effects on survivorship in two species of *Sceloporus* lizards over the four-week time span of this study. This duration of paint application is within the range of time we use paint marking in our research. In addition, both types of paint remained visible on the dorsum of both species for at least four weeks.

Several important differences may explain why we found no effect of xylene-based paints on survivorship and growth while the earlier study did. *Uta stansburiana* may be more sensitive to xylene than *S. virgatus*. Both studies used a relatively wide range of body size and thus differences in our results are not likely to be attributable to differences in the body size of these two species. Our study was conducted early in the active season, while the *U. stansburiana* study was conducted in October, later in the active season for many species of lizards. In addition, *U. stansburiana* were re-painted up to four times over a two-week period, whereas we painted almost all of our lizards only once (two of 25 required a second application of xylene paint). Frequent markings may have increased exposure to xylene or other toxic substances in the paint beyond some threshold for *U. stansburiana*. Furthermore, we handled lizards once per week for four weeks, whereas *U. stansburiana* were handled at least four times over two weeks. Frequent handling can elevate plasma corticosterone levels in lizards (Abell and Hews 1999; Moore et al. 1991). Thus, differences in handling regimes and stress responses to handling may have contributed to differences in the survivorship of *S. virgatus* and *U. stansburiana*. In summary, the single application of xylene-based paint used in our study had no measurable effect on survivorship over four weeks. However, if experiments require animals to be marked multiple times over a short period, a non-xylene-based paint may be more appropriate. In addition, a latex-based paint may be more desirable because it may be more environmentally friendly than a xylene-based paint.

Acknowledgments.—This research was funded by grants to VSQ from the Indiana State University Graduate Student Fund and the Theodore Roosevelt Fund of the American Museum of Natural History (NY). We thank P. Scott, P. Zollner, and two anonymous reviewers for helpful comments on the manuscript. We have complied with institutional Animal Care guidelines at Indiana State University (ISU-IACUC Protocol # DH:99-3) and the Southwestern Research Station, of the American Museum of Natural History, and required state and federal permits were obtained from Arizona and New Mexico.

Keeping the Frogs Still: Orajel® is a Safe Anesthetic in Amphibian Photography

HINRICH KAISER
Department of Biology, La Sierra University, Riverside, California 92515-8247, USA
e-mail: hkaiser@lasierra.edu

and

DAVID M. GREEN
Redpath Museum and Department of Biology, McGill University, Montréal, Québec H3A 2K6, Canada
e-mail: david.m.green@mcgill.ca

The use of the teething ointment Orajel® has been described twice in herpetological publications (Altig 1980; Chen and Combs 1999). In both of these papers, the authors extol the virtue of Orajel® in providing a humane method of terminal anesthesia for amphibians or even small reptiles. We here describe the utility of Orajel® and Anbesol® in aiding photographers with the challenge of maintaining their photographic subject in a stable position.

Orajel® and Anbesol® are over-the-counter medications that alleviate pain in teething infants or during other mouth- and tooth-related ailments. Both exist as infant and adult versions that differ in the concentration of the active ingredients. Both are available in the United States with benzocaine at concentrations of 7.5% and 20%. The small tubes of Orajel® and Anbesol® (gel content 7.08 g) are easily transported and, as Altig (1980) noted, do not require special permits for international or even national travel, unlike many other anesthetics commonly used by herpetologists and which are listed as controlled substances (e.g., nembutol). Small amounts of Orajel® applied to the head (Altig 1980), the venter, or both (Chen and Combs 1999) have been effective in killing both salamanders and frogs conveniently. Oral application of these products in amphibians may accelerate the anesthesia.

During work on the small Caribbean frogs in the genus *Eleutherodactylus* (Leptodactylidae), we grappled with the problem of photographing specimens in the field as well as in the lab. In the field, the obvious challenge was to keep a frog still in its natural habitat or in a natural setup. In the lab, the challenge was not to lose an escapee behind laboratory benches and equipment while attempting photography in a controlled environment. Both of these challenges were easily alleviated on these small (30–40 mm SVL) frogs by using pinhead-size dollops of Orajel® and the following approach.

Frogs were captured and interned in a small plastic container. After the photo shoot was set up, a frog was removed from the container, and the Orajel® applied to its head by gently distributing the gel in the interocular area. Timing is critical at this point,

especially if the frog is to remain alive. After application of the gel, the frog was placed on the substrate and was encouraged to "take the last step," to position itself naturally. Within 30–60 s of gel application, frogs remained still for photo shoots limited to 2 min. Immediately after the photo shoot, frogs were rinsed gently with water from a spray bottle, and any remaining gel was removed from the head by gentle rubbing. Frogs were allowed to recover on dripping wet paper towels in plastic containers. Full recovery of sometimes motionless individuals occurred invariably within 15 min. This technique was used successfully with frogs in the genera *Bufo, Colostethus, Eleutherodactylus, Flectonotus, Hyla, Leptodactylus, Physalaemus*, and *Scinax*. The largest of these was an adult female *Leptodactylus fallax* (SVL 220 mm), which required two applications, whereas the smallest was an adult male *Eleutherodactylus pinchoni* (SVL 18 mm). It should be noted that our work was carried out on a limited, albeit large, sample of primarily neotropical frogs. No fatalities occurred in our trials, but we cannot overemphasize that the possiblity of an overdose always exists.

Photographers often rinse amphibians to ensure the proper moisture and the appropriate light reflection on the animal. Application of the gel in a thin layer does not provide a distraction to the light, but blends in well. We have occasionally observed some slight skin discolorations after gel applications, and this is undoubtedly due to the release of skin products. However, this seems to be an individual response rather than a species-level response, and our technique has been tested on a large number of frogs. One concern with photography is the stress caused by handling animals frequently in an attempt to position them as desired. Though lacking empirical data, we believe that our technique may reduce handling stress because handling is minimized and the frog is in an anesthetic daze during the photo shoot.

Salamanders of the family Plethodontidae are found in late-successional deciduous forests of northeastern North America. One representative of the family, *Plethodon cinereus* (the redback salamander), ranges from Ontario and Newfoundland in the north, to Indiana and North Carolina in the south (Petranka 1998). Redback salamanders are found commonly under logs, leaf litter, and rocks (Harding 1997) in habitats that remain moist (Jaeger 1971). *Plethodon cinereus* is believed to be most active at night, and during or directly after rainfall (David and Jaeger 1981). Under the dense canopy of late-successional hardwood forests, night-time light intensities, primarily produced by the moon, obscure or eliminate visual cues. Therefore, the study of the behavior of *Plethodon cinereus* would be facilitated if procedures were developed in which visual observation by human experimenters was possible, but salamanders with intact visual systems could not detect visual cues. This would occur under lighting conditions in which the specific wavelengths provided were detectable by humans, but not by redback salamanders. We hypothesized that black light might provide such wavelengths, and this experiment was conducted to verify that visual stimuli are not detected by *P. cinereus* under black light. The absence of this ability would allow the simulation of "night-time" conditions in future experiments.

Forty redback salamanders were collected from a late successional hardwood forest near the town of Big Bay, Powell Township, Marquette County, Michigan. Upon collection, specimens were placed individually in jars and were transported to laboratory facilities at Northern Michigan University. Salamanders were housed individually in petri dishes lined with damp filter paper and were stored in a controlled temperature chamber at 18 ± 0.5°C with a Light:Dark cycle of 12:12 (Jaeger and Gergits 1979). Salamanders were fed *Drosophila melanogaster* to satiation twice per week. Subjects were maintained under these conditions for a minimum of one week before experimental trials were conducted.

The 40 salamanders were assigned randomly to two groups of 20 for testing, either under fluorescent light (wavelength range of 400–700 nm) or black light (wavelength range of 4-400 nm). Lights were suspended approximately 70 cm above the test arena. Test specimens were placed into the test arena (i.e., a 30 x 24 x 9 cm plastic box) and permitted to acclimate under a petri dish for 1 min, after which the petri dish was removed and the subject was observed for 2 min. A visual stimulus in the form of a black fish-

ing lure hooked to a clear fishing line was bobbed approximately 4 cm in front of each specimen every 30 sec for a total of four times. The experimenter was concealed behind a blind to prevent any additional visual cues. The visual stimulus produced no auditory or chemical cues that could be detected by the observer. Test arenas were moistened with distilled water and washed with a clinical detergent powder (Alconox) after each trial to prevent deposition of chemical cues by subjects.

We predicted that redback salamanders would respond to the visual stimulus under fluorescent light but would show no change in behavior after exposure to the visual stimulus under black light. This would indicate an inability to detect visual cues in the latter condition. Behaviors monitored included changes in direction of movement, stops in movement, looking towards or up at the visual stimulus, and no response. A change in direction occurred when a test subject would alter its original course in response to the visual stimulus. When a salamander would cease movement upon encountering the visual stimulus, the behavior was recorded as a stop in movement. If a test subject lifted or turned its head in the direction of the visual stimulus, the behavior was recorded as looking. If a salamander did not deviate from the behavior it was exhibiting before the introduction of the visual stimulus, the behavior was recorded as no response.

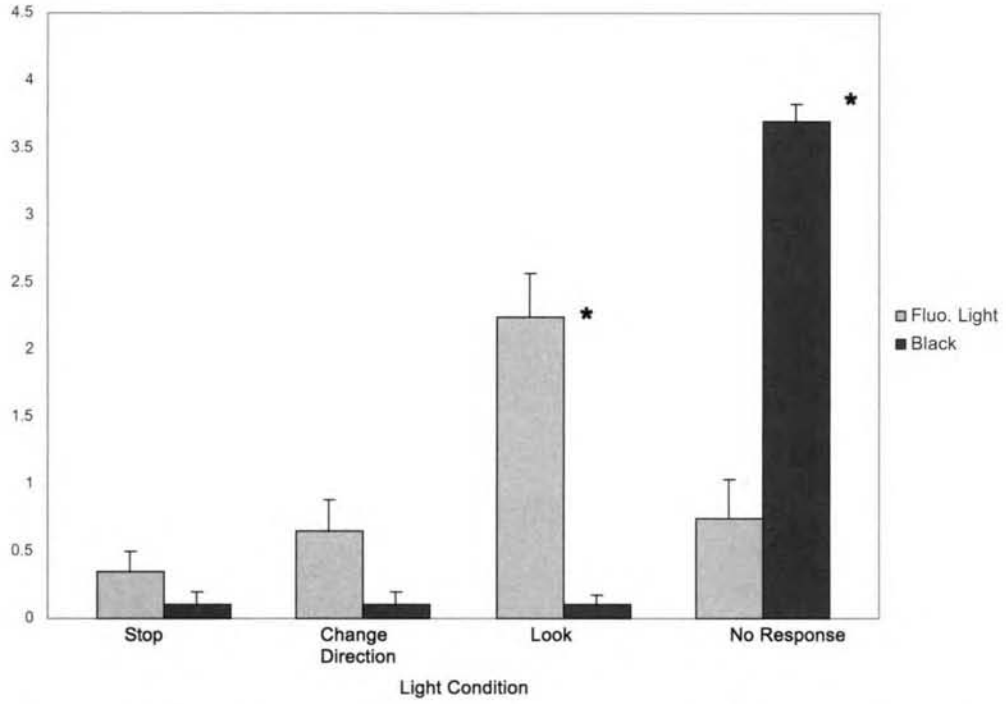

FIG. 1. The mean ± SE number of responses to visual stimulus under fluorescent and black light by *Plethodon cinereus*. An asterisk (*) indicates a significant difference of $P < 0.05$.

Data were not normally distributed. Therefore, responses under the two light conditions were compared using Mann-Whitney Rank Sum Tests (Sokal and Rohlf 1995). Figure 1 shows the mean number of responses ± standard error (SE) for stopping, changes in direction, looking, and no response under fluorescent light and black light. The frequency of stopping ($T = 448.5$; $P = 0.300$) and direction change ($T = 464$; $P = 0.146$) were not significantly different between conditions. Subjects under fluorescent light looked significantly more than salamanders tested under black light ($T = 573$; $P < 0.001$). Salamanders tested under black light exhibited no response to the visual stimulus significantly more often than animals tested under fluorescent light ($T = 235.5$; $P < 0.001$).

This experiment showed that redback salamanders responded to visual stimuli under broad spectrum fluorescent light significantly more than to the same visual stimulus under black light. Under fluorescent light, test subjects looked in the direction of the visual stimulus. Under black light, salamanders continued behaving as before, and appeared oblivious to the visual stimulus. Fifteen of 20 salamanders tested under black light never responded to the visual stimulus during their trials. In comparison, only two out of 20 salamanders tested under fluorescent light did not respond to the visual stimulus ($\chi^2 = 17.28$; $P < 0.001$). Of the five animals that did respond under black light, four of them responded only once out of the four times the visual stimulus was introduced into their test chamber. The stimulus used may have created a breeze as it was swung past the salamanders, which may have elicited a response. These observations and empirical evidence suggest that redback salamanders are unable to detect visual stimuli under black light. This method for eliminating visual cues can be used to simulate "night-time" conditions in the laboratory while allowing observation by experimenters.

Acknowledgments.—We thank Nathan Forst and Peter Froiland for assisting in the collection of salamanders. In addition to funding from the Department of Biology at Northern Michigan University, this research was supported by a Charles C. Spooner Grant and an Excellence in Education Grant from Northern Michigan University.

Using a Water Bath to Rear Eggs of the Marbled Salamander, *Ambystoma opacum*

SCOTT D. SMYERS*

Pond-breeding amphibians are commonly used as study organisms in many developmental, behavioral, and ecological studies. Techniques for rearing the eggs of salamanders with complex life-cycles have been described previously (Houck et al. 1985; Vess and Harris 1997). Bernardo and Arnold (1999) described using a device, originally developed for salmonid eggs, to rear eggs of a stream-side salamander, *Desmognathus ocoee*. This device (egg washer) was characterized as a series of interchangeable plastic trays with removable screened lids in which water was pumped up through each tray and continuously circulated through the system. Bernardo and Arnold (1999) tested the egg washer over two seasons with a hatching success of 35.2% for the first and 54.2% for the second season. The use of a mass rearing apparatus for eggs of amphibians can be advantageous for several reasons including low maintenance, application to large numbers of eggs in a homogenous environment, and reduced handling of eggs (Bernardo and Arnold 1999).

We developed a mass rearing technique for the eggs of the marbled salamander, *Ambystoma opacum* (Ambystomatidae). Female *A. opacum* deposit their eggs under cover objects (e.g., logs and rocks) in dry basins of ephemeral ponds. Embryos develop to the hatching stage (stage 46: Harrison 1969) in 9–15 days, but they may remain within the eggs for up to 3–4 months before hatching (Petranka and Petranka 1981). Petranka et al. (1982) demonstrated that the physiological trigger for hatching in embryos of *A. opacum* is oxygen deprivation across the egg membrane. Thus, in natural conditions, hatching occurs when the eggs are inundated as the pond fills. We tested three hypotheses: 1) a well-aerated aquatic environment will not initiate hatching of eggs of *A. opacum*, 2) successful hatching of *A. opacum* embryos is equal in both Petri dishes and a well aerated aquatic environment, and 3) temperature manipulation can be used to control the rate of development.

Our rearing system (see Fig. 1) was comprised of a glass tank (25 x 50 x 30 cm) containing 22 cm of dechlorinated water. A section of tubing was attached to each rear corner of the tank and air stones were fitted to the lower end of each tube 5 cm from the bottom. Separate pumps provided air to each tube. An underwater pump and filter unit (Model 26199, Whisper, Blacksburg, Virginia, USA) was placed on the bottom of the tank in the center, which provided charcoal and particulate filtration. We placed the filter into a plastic container filled with gravel to keep the filter from floating to the surface. A third air pump was used to supply air to the filter.

Eggs from seven clutches (N = 422 eggs) were collected from an ephemeral pond in Evangeline Parish, Louisiana, USA from 25 November–8 December 1999. Because of the weather conditions and migration patterns observed during this season in and around the ephemeral pool, we believe that the clutches we collected were deposited no more than 48 h prior to our collection, thus we believe these clutches were approximately in the same stage of development. We mixed the eggs together to remove any clutch affect from the experiment and randomly (i.e., haphazardly) assigned eggs to each treatment. Eggs were introduced into the tank apparatus (i.e., egg bath) in hinged-lid polyethylene vials (22 x 32 mm; Ward's, Rochester, New York, USA). Prior to placing the eggs into the cylinders, we drilled 10 1-mm holes in both ends and 40 1-mm holes evenly spaced along the edges so that water could flow through the cylinder. We placed 10 eggs in each cylinder and introduced 10 cylinders into the egg bath. When we placed the cylinders into the water, they filled with water but remained floating so that a portion of each cylinder was at the surface of the water. The bubbles from the aeration did not cause enough disturbance to move the cylinders and they remained relatively stationary once placed into the egg bath. We set up two egg baths (100 eggs each), each in a separate environmental chamber (Model 3740, Forma Scientific, Inc., Marietta, Ohio, USA). We maintained one chamber at 11°C and the other at 16°C. We periodically observed each bath and added water as needed to maintain a constant volume. We removed from the cylinders newly-hatched larvae and determined stage of development (Harrison 1969) using a dissecting microscope. Features could be identified without sacrificing the larvae.

Additionally, we evaluated survival and hatching success of eggs reared under normal atmospheric conditions. We placed 10 eggs, each from the same mixed collection as used in the egg bath treatment, into a Petri dish (14.5 x 2.5 cm: N = 20) with a damp filter paper substrate. We rotated and misted the eggs every three days and changed the filter paper periodically. We placed one set of 10 Petri dishes, each with 10 eggs, in the 11°C chamber and the other set of 10 in the 16°C chamber. We monitored the Petri dishes on the same schedule as the egg baths.

We maintained the egg baths and Petri dishes from 8 December 1999–16 March 2000. On 16 March 2000 (Day 99) we removed the eggs from the environmental chambers and placed eggs from each replicate (i.e., cylinder or dish) into separate containers filled with water from the egg bath. We then monitored the number of individuals that hatched in each treatment and removed any visibly dead embryos or hatched individuals. We placed the eggs in the egg bath water, thus allowing the temperature of the water to slowly increase to 23°C, minimizing the stress of changing the temperature on the embryos as well as allowing for the decrease in dissolved oxygen to occur gradually.

We determined that a well-aerated aquatic environment did not initiate hatching of eggs of *A. opacum*. We conducted a two-way ANOVA (PROC GLM; SAS Institute, 1994) with $\alpha = 0.05$, to evaluate the differences in hatching success between Petri dishes and cylinders in each environmental chamber. The results of the ANOVA indicated that there was not a significant interaction effect between temperature and condition ($F_{1, 36} = 0.75$, $P = 0.3911$) on egg survival to hatching. Furthermore, when the interaction

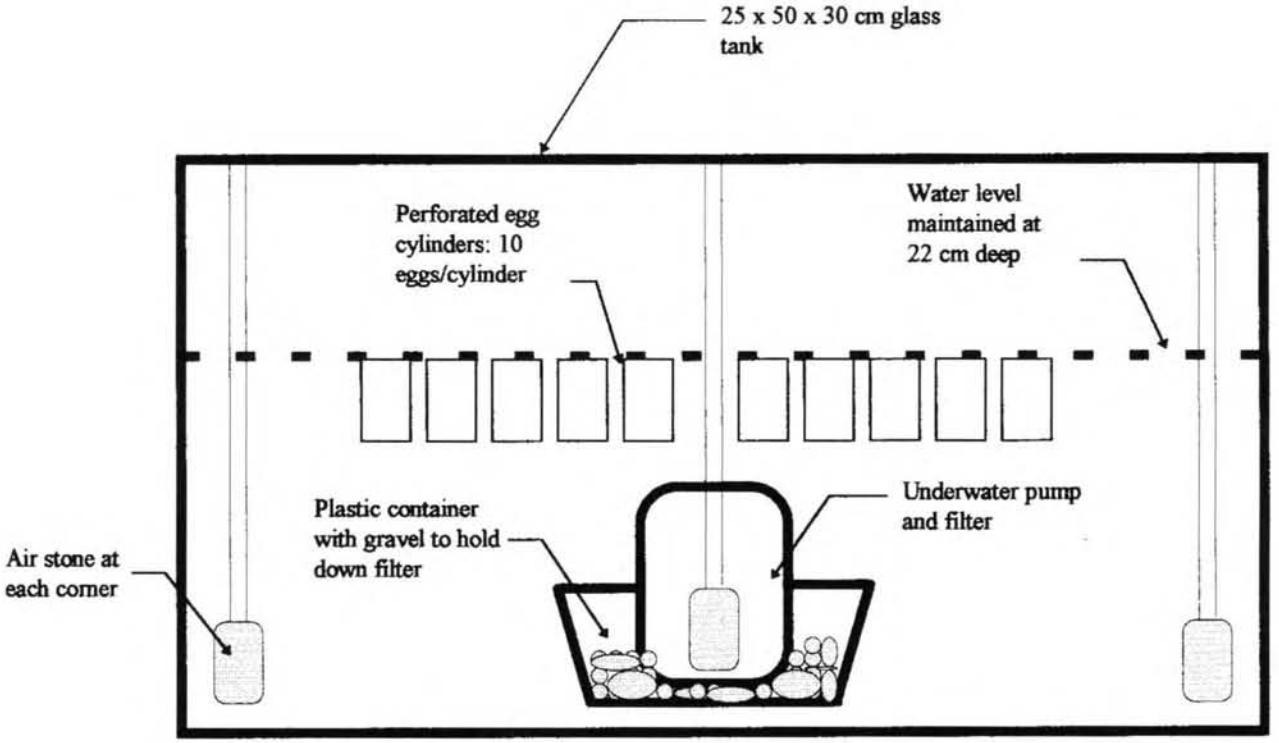

FIG. 1. Schematic diagram of water bath used for rearing eggs of *Ambystoma opacum*.

was removed from the model, temperature did not have a significant effect on egg survival to hatching ($F_{1,37} = 0.76$, $P = 0.3894$). However, environmental condition had a significant effect on egg survival to hatching (mean ± 1 SE; egg bath = 8.5 ± 0.34 larvae per cylinder; Petri dishes = 6.6 ± 0.79 larvae per cylinder) ($F_{1,37} = 5.13$, $P = 0.0295$).

Eggs did hatch prematurely in the egg bath (11 in the 11°C bath and 33 in the 16°C bath). The aqueous environment provided in the bath allowed for survival of larvae until our next observation when we removed any larvae that had hatched. Conversely, prematurely hatching larvae in the Petri dishes (5 in the 11°C chamber and 4 in the 16°C chamber) did not survive. Larvae that hatched before induced hatching in the 16°C egg bath ranged from stage 43 to 46. One individual hatched at stage 43, 25 individuals hatched at stage 45, and 7 individuals hatched at stage 46. Larvae that hatched before induction in the 11°C egg bath ranged from stage 40 to 45, with five individuals at stage 40, two individuals at stage 42, and four individuals at stage 45. Although these data are qualitative, there appears to be a trend in that the stage of development in embryos reared in cooler conditions is earlier than those raised at higher temperatures. We suggest that fewer eggs would have hatched prematurely in the egg baths if our laboratory had not experienced an unexpected power failure on 10 January 2000 (Day 33). Aeration was not operating for approximately 5 h. During that 5 h period, 19 larvae hatched from the 16°C egg bath and 7 larvae hatched from the 11°C egg bath. We returned the eggs to egg baths when the power was turned back on.

The results of this experiment support our prediction that eggs of *Ambystoma opacum* can be reared underwater in well-aerated conditions. We found that embryonic survival in the egg bath was significantly different (higher) than eggs reared on damp filter paper. We also report that embryos reared at 11°C appeared to develop slower than those incubated at 16°C.

We believe this technique could be an inexpensive (approx. US $30 per egg bath) and valuable method for the mass rearing of amphibian eggs for research in developmental biology, for investigations of delayed hatching mechanisms in eggs of amphibians (sensu Martin 1999), and in community ecology experiments using larval amphibians as study organisms where it is important to control the homogeneity and timing of hatching of eggs.

Acknowledgments.—We thank R. Jaeger, V. Townsend, Jr., and J. Marshall for reviewing earlier drafts of this manuscript. Eggs were collected under permit LNHP-99-020 provided by the Louisiana Department of Wildlife and Fisheries. This work was partially supported by funds from the Graduate Student Organization at The University of Louisiana at Lafayette.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 32, Number 1 (March 2001). Submissions should be directed to one of the section editors (contact information located on inside front cover of this issue), as follows: amphibians (Painter); lizards, amphisbaenians, crocodilians, *Sphenodon* (Hauge); snakes and turtles (Butterfield).

CAUDATA

AMBYSTOMA MACULATUM (Spotted salamander). **REPRODUCTION**. Egg masses of spotted salamanders (*Ambystoma maculatum*) can either be clear, white, or intermediate in color depending on the presence of proteins in the outer jelly layers (Hardy and Lucas 1991. Comp. Biochem. Physiol. 100A:653–660; Ruth et al. 1993. J. Herpetol. 27:306–314). Ruth et al. (*op. cit.*) found no adaptive advantage of white versus clear masses, whereas Brodman (1995. J. Herpetol. 29:111–113) found that white masses contained more eggs on average than clear masses. Often the outer jelly membrane surrounding the eggs of *A. maculatum* is colonized by a symbiotic, unicellular green alga (*Oophila amblystomatis)* that increases oxygen supply to the developing embryos (Gilbert 1942. Ecology 23:215–227; Gilbert 1944. Ecology 25:366–369; Gatz 1973. J. Herpetol. 7:137–138; Bachman et al. 1986. Can. J. Zool. 64:1586–1588; Pinder and Friet 1994. J. Exp. Biol. 197:17–30).

Five clear and five white *A. maculatum* egg masses were collected at random on 9 March 2000 from a small seasonal wetland located on the Pine Ridge Country Club in Edgefield County, South Carolina, USA. Color of each mass and eggs was recorded (Table 1). When possible, the number of eggs per mass was counted (Table 1); however counting the number of eggs of larger masses was not possible without destroying the mass. Egg masses were kept in separate containers with fresh water. Within four days after collection some embryos began to hatch. The number of hatchlings from each mass was recorded (Table 1), dead larvae or eggs that were clearly not viable were discarded, and live hatchlings were released.

This study corroborates Brodman's (*op. cit.*) finding that white masses contained more eggs than clear ones. However, in contrast to Ruth et al. (*op. cit.*), this study found that clear egg masses had significantly better success than white masses ($p = 0.04$). Ninety-six larvae hatched from clear masses (mean = 19.2), and 29 larvae hatched from white masses (mean = 5.8).

TABLE 1. Color and number of eggs in *Ambystoma maculatum* egg masses and the number of eggs that hatched from each mass.

Mass No.	Color	No. of eggs	No. hatched
1	clear w/green eggs	31	21
2	clear w/green eggs	19	6
3	white/green	>50	0
4	white/green	>50	4
5	white/green	>50	0
6	clear	22	20
7	white	>50	8
8	clear w/green eggs	>50	9
9	white w/green eggs	>50	17
10	clear	>50	40

Seven egg masses (1–5, 8, and 9) that were colonized by *O. amblystomatis* had little to no success. Only 57 (mean = 8.1, min = 0, max = 21) eggs hatched from these seven masses. Sixty-eight larvae hatched from three masses (6, 7, and 10) that were not colonized by *O. amblystomatis* (mean = 22.6, min = 8, max = 40). Significantly more embryos hatched from the non-colonized masses than from the algae-colonized masses ($p = 0.04$).

Three of the masses (3, 4, and 5) appeared to be completely covered with algae, and only four larvae hatched from these three masses. Possibly the algae could have been one or more species other than *O. amblystomatis* that were detrimental to the development of the embryos. Four masses (1, 2, 8, and 9) that contained colonies of *O. amblystomatis* around individual eggs, but not completely encasing the mass, produced 53 larvae.

One conclusion from this study is that differential success of *A. maculatum* egg masses can be variable among locations and is probably dependent on a suite of environmental conditions that were not measured in any of the studies.

EURYCEA CIRRIGERA (Southern Two-lined Salamander). **LARVAL HABITAT**. Larval two-lined salamanders typically inhabit lotic environments (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press. Washington, D.C. 587 pp.). Larval *Eurycea bislineata* from New York (Bahret 1996. J. Herpetol. 30:399–401) and larval *E. wilderae* from North Carolina (Bruce 1982. Copeia 1982:117–127), however, have been reported from lentic environments. We found larval *E. cirrigera* inhabiting a small farm pond (surface area 177 m^2, max. depth 1.5 m) 2.5 km NNW of Hinton, West Virginia, USA, at 812 m elevation. The pond was located in mesic woods and supported populations of several amphibian species. This note represents the first report of larval *E. cirrigera* inhabiting a lentic environment and the first to provide size at metamorphosis from West Virginia.

Snout-vent lengths (SVL) of larvae were measured to the nearest 0.1 mm and are reported here as means ± 1 SD (range): 11 August 1994 (N = 103) 12.35 ± 1.93 mm (9.8–20.0 mm); 30 October 1994 (N = 51) 20.01 ± 1.61 mm (17.0–23.7 mm); 17 January 1995 (N = 85) 20.05 ± 1.72 mm (16.4–26.0 mm); 19 March 1995 (N = 51) 20.95 ± 2.16 mm (17.6–27.4 mm). Average growth rate for this 220-day period was 0.039 mm/day, however larvae grew very little during the winter months.

Sixty *E. cirrigera* metamorphs were collected in pitfall traps on the banks of the pond between 20 July and 3 August 1993. These recently transformed juveniles were apparently leaving the aquatic environment to inhabit the surrounding forest. Metamorphs measured (SVL) 22.31 ± 1.94 mm (18.3–27.0 mm).

Over 15,000 man-made farm ponds exist in West Virginia (Core 1966. Vegetation of West Virginia. McClain Printing Co. Parsons, West Virginia. 217 pp.), many of which play important roles in the ecology of aquatic and semi-aquatic amphibians (Lively and Bayless 1972. Proc. West Virginia Acad. Sci. 44:89–92). Our observations suggest that farm ponds may play a more important role in the ecology of *E. cirrigera* than previously recognized.

We thank Michele L. Brophy, Peter A. Kramer, and James W. Barron for their assistance in the field and laboratory, and Joseph C. Mitchell for reviewing the manuscript. Voucher specimens were deposited in the West Virginia Biological Survey collection at Marshall University (WVBS 6902–6906). Specimens were collected under WVDNR permit numbers 33-1993, 19-1994, and 52-1995.

Submitted by **TIMOTHY R. BROPHY*** and **THOMAS K. PAULEY**, Department of Biological Sciences, Marshall University, Huntington, West Virginia 25755-2510, USA. *Present address: Department of Biology, George Mason University, Fairfax, Virginia 22030-4444, USA.

SALAMANDRINA TERDIGITATA (Spectacled Salamander). **TERRESTRIAL OVIPOSITION.** During research for the Atlas projects of amphibians and reptiles of Latium (Bologna et al. 2000. Anfibi e rettili del Lazio. Palombi, Roma. 159 pp.) and Rome (Bologna et al., *in prep.*), data on *Salamandrina terdigitata* were collected at several localities which included the first record from the urban area of Rome.

The spectacled salamander is protected by national and European laws. It appears to be widespread in the Apennines, especially near Latium where more than 100 localities have been reported. The species occurs at middle elevations (200–1300 m) along river and stream valleys in mesic or submesic forests. A few populations have been reported as low as 20–80 m, three of these near Rome, and another near Tarquinia (Viterbo province).

A population of *S. terdigitata* was reported from the Insugherata Regional Natural Reserve in the NW part of Rome. This population is located in an isolated chestnut woodland of *Castanea sativa* and *Ostrya carpinifolia* at ca. 80 m elev. along a perennial stream. The species was first reported from this site by local people in 1983, its presence was confirmed in November 1997, and the population has been under study since 1999.

On 6 and 10 April 1999 we observed two individuals lay eggs on the ground under a stone 30 m from the water. These clutches of two and three eggs were observed for 15 days until they were attacked by fungus. After that they were transferred to the laboratory and placed in fresh water although none of the eggs hatched.

Salamandrina terdigitata usually spawns in the water, sticking the eggs to the substrate, and the development includes aquatic larvae. This is similar to other genera in the family Salamandridae (Duellman and Trueb 1986. Biology of Amphibians. McGraw Hill, New York. 670 pp.). Eggs are normally laid from March to May, although the reproductive period may extend from late December into early June. At Insugherata, 121 egg clutches have been observed between 2 March and 8 May. All have been deposited in a sandy stream with sparse vegetation. Eggs were deposited under stones, on the sides of stones, or under submerged branches. Hatchings have been observed between 8 April and 30 May and larvae metamorphosed between 15 June and 25 July.

Oviposition on the ground or direct development of young is common in Plethodontidae or in salamandrids of the genus *Salamandra* (*lanzai*, *atra*, *luschani*, and some mountain populations of *salamandra* and *caucasica*). Although it is unknown if hatching and metamorphosis would have been successful, this is the first report of terrestrial oviposition in *S. terdigitata*.

We thank Paolo Macedone for information on the 1983 record, Marzio Zapparoli for the 1997 record and help with field work, Francesca Della Rocca for the research collaboration, and Alberto Venchi for suggestions. We also thank the RomaNatura Board, which administers the Insugherata Regional Park, for permission to conduct research at that site.

Submitted by **LEONARDO VIGNOLI** and **MARCO A. BOLOGNA,** Dipartimento di Biologia, Università degli Studi "Roma Tre", viale Marconi, 446, 00146 Roma, Italy (e-mail: bologna@bio.uniroma3.it).

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). **PREDATION.** Predators of *Siren intermedia* are poorly documented (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press. Washington, D.C. 587 pp.). The following observations from Mingo National Wildlife Refuge, Stoddard Co., Missouri, USA, represent the first documentation of a mink and great egret preying upon *S. intermedia*.

On 21 February 1999 at 1400 h, we observed a mink (*Mustela vison*) on a clump of vegetation in a large pool consuming a *S. intermedia*. After we watched the mink eat for ca. three minutes, the mink placed the uneaten portion of the siren beside it and curled up, presumably to rest. We then disturbed the mink and retrieved the remainder of the still-moving, uneaten siren. The uneaten portion consisted of the posterior end of the animal extending to just anterior of the vent (113 mm and 27 g). Based upon measurements of other individuals, the estimated size of this siren was >300 mm TL and >80 g. The uneaten portion of the siren was catalogued as University of Missouri-Columbia (UMC) 6844.

On 16 April 1999 at 1430 h we observed a great egret (*Casmerodius albus*) eating a lesser siren ca 170–200 mm TL. The egret seemed to have difficulty handling the siren because it was squirming, but eventually swallowed it whole. The event lasted less than one minute. We observed another great egret consuming a lesser siren on 17 April at ca. 1700 h. This siren was larger (ca. 280–320 mm TL) than the one eaten on the previous day. Perhaps due to the increased size of the siren, the egret seemed to have a more difficult time swallowing it. The egret eventually swallowed the siren whole, but it took ca. 3 minutes to consume the animal.

We thank R. F. Wilkinson and A. Mathis for reviewing this manuscript.

ANURA

ACRIS CREPITANS (Northern Cricket Frog). **ATTEMPTED CANNIBALISM.** Cannibalism is an important strategy for resource allocation in any population. Cannibalism in *Acris* can reduce an individual's inclusive fitness through kin selection (Polis. 1981. Ann. Rev. Ecol. Syst.), and reduce individual survivorship

via accumulated toxins and parasites (Pfennig et al. 1991. Oecologia 88:161–166). On 17 July 2000 at 1500 h while on Janes Creek in the vicinity of Ravenden Springs, Randolph County, Arkansas, USA, a large (28.2 mm SVL) adult *A. crepitans* was observed during an attack on a newly metamorphosed (12.4 mm SVL) *A. crepitans*. The juvenile jumped to escape capture, but landed immediately in front of an adult. The adult alertly lifted its body off the ground and flicked its tongue at the juvenile. The adult grabbed the tibio-tarsal portion of the juvenile's left rear leg and proceeded to swallow the juvenile. At this point the juvenile placed the plantar area of its right rear foot on the nose of the adult. The prey then pulled the left leg out of the adult's mouth by straightening the right leg. Immediately upon escaping the grasp of the adult, the juvenile rapidly jumped away. Because juvenile *A. crepitans* emerge in huge numbers (as many as three frogs per 0.3 square meter at this location), it is possible that predation by metamorphic frogs significantly reduces populations of small insect prey utilized by all age classes. In this way, the costs of cannibalism depicted above would be out-weighed by reduced food supply causing adult animals to occasionally prey upon juveniles. The life span of *A. crepitans* is about a year (Gray 1971. Ph.D. dissertation, Illinois State Univ.), and adult populations are quite small during juvenile emergence from streams (*pers. obs.*) suggesting that selective pressure on adults to avoid cannibalism may not be severe. The small numbers of adults compared to metamorphs, combined with this species' high activity levels and erratic jumping patterns may explain why cannibalism has not been previously observed. Whether the juvenile actually forced itself from the adult's grasp, or if the adult let it go, could not be determined. Both specimens are deposited in the Arkansas State University Herpetology Museum (ASUMZ 24724, 24716).

ASCAPHUS TRUEI (Tailed Frog). **PREDATION.** Predators of *A. truei* are not well known. Jones and Raphael (1998. Herpetol. Rev. 29:39) reported predation of a metamorphosing *A. truei* by a hellgrammite (Megaloptera), and in a separate observation, a Cope's giant salamander (*Dicamptodon copei*) preying on a metamorphic *A. truei*. Leonard et al. (1993. Amphibians of Washington and Oregon, Seattle Audubon Society, Seattle, Washington. 166 pp.) noted that tailed frog larvae are an important prey species for Pacific giant (*Dicamptodon tenebrosus*) and Cope's giant salamanders.

The observation reported herein was made in a managed forest at McDonald Creek (T10N, R1E, Sec. 5, NE1/4, NW1/4, SE1/4) in Humboldt County, California, USA. McDonald Creek is a NW-facing, second-order, fish-bearing stream. The stream at that location was 1.7 m wide, and 0.2 m deep at thalweg. The air temperature was14.6°C at 1400 h and the stream temperature was 13.7° C at 1415 h. At 1347 h on 23 June 1997, I observed a common garter snake (*Thamnophis sirtalis*) with an *A. truei* in its mouth. The snake was on a log on a gravel bank, 0.5 m from the edge of the creek. The frog was being swallowed headfirst and approximately half of its body was in the snake's mouth. The snake became aware of my presence, dropped the frog, and retreated into the vegetation. The *A. truei* landed on its back and made no attempt to escape. An opaque mucous covered the frog, but the animal was still alive. The frog was an adult male 36 mm SVL. I rinsed the frog and saw no evidence of injury. I released it on the bank, and it escaped into the stream.

All age classes of *A. truei* have been found in McDonald Creek during electrofishing surveys and time-constrained searches for amphibians. *Dicamptodon tenebrosus* larvae and paedomorphs have been detected in the mainstem and *Rhyacotriton variegatus* larvae and adults have been found in the headwaters of McDonald Creek and its tributaries. *Thamnophis sirtalis* have been documented (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest, University of Idaho Press. 332 pp.) feeding on several species of frogs and salamanders, but I found no reports of the species as a predator of *A. truei*.

I thank Hartwell Welsh and Lisa Ollivier for helpful comments on this note.

BUFO BUFO (European Common Toad). **RED ANT PREDATION**. The common toad, *Bufo bufo*, occupies a variety of habitats and is one of the most widely distributed and common amphibians of the Paleartic region (Borkin and Veith 1997. *In*: Atlas of Amphibians and Reptiles in Europe, pp. 118–119. Paris, Societas Europaea Herpetologica and Muséum National d'Histoire Naturelle [IEGP/SPN]). Anuran amphibians are important components of the diet of vertebrates and invertebrates (e.g., Dolce 1983. Atti Mus. civ. Stor. nat. Trieste 35: 313–328; Gleed-Owen 1996. Brit. Herpetol. Soc. Bull. 57: 21–23; Kehr and Schnack 1991. Alytes 9:61–69; Zahn 1997. Salamandra 33:89–91).

Herein I report multiple cases of predation by *Formica rufa* (Insecta: Hymenoptera: Formicidae) on newly metamorphosed common toads (*Bufo bufo*) in a mountain lake of the northeastern Alps. The study area is Lago di Tovel, 1178 m elev., within the Adamello-Brenta Natural Park, Trento province, northeastern Italy. Observations were carried out during 8–9 Aug 1997, from 1030 to 1645 h and from 1115 to 1550 h, with no wind and a clear sky. During this time, hundreds of *Bufo bufo* tadpoles and toadlets lived in the shallow waters and around the lake borders. Most of the tadpoles were nearing metamorphosis and several toadlets were moving around the lake margin and along the forest edge.

Along a transect ca. 50 m long I counted 37 *Bufo bufo* toadlets attacked by one or two *Formica rufa*. In 33 of 37 cases, the ants had attacked the hindlimbs; in the other four instances the ants were at the flanks of the toadlets. All *Bufo bufo* were still alive. In most cases (29 of 37) the ants were within 30–45 cm of a nest opening, so it is likely that the attack occurred a few minutes prior to my observation. The defensive reaction of a toadlet to an ant bite included: 1) an immediate push-back movement of the hind-leg that temporarily stopped the ant attack, and 2) a twisting of the

body to avoid the ant bite again. The ant then successfully repeated the attack and carried the toadlet to the nest opening.

Franco Andreone (Regional Museum Natural History, Turin) and Kurt Grossenbacher (Naturhistorishes Museum, Bern) kindly commented upon a draft version of the manuscript. This short note is dedicated to my young sons Silvia and Claudio, ages 7 and 3.5 yrs, who reported this observation to me.

BUFO CANORUS (Yosemite Toad). **LARVAL CANNIBALISM.** On July 1999, I observed *Bufo canorus* tadpoles eating a conspecific in Inyo National Forest, Mono County, California USA. In a small, shallow pool of water in the meadow along the west edge of Cloverdale Lake (37°33'N, 118°53'W; 3150 m elev.) two tadpoles were consuming a dead conspecific tadpole of the same size. I could not determine if the tadpole was dead prior to cannibalism, or if it was killed by the conspecific tadpoles and then consumed. The dead tadpole showed no signs of decay. Cannibalism occurs among anurans (Crump 1983. Amer. Nat. 281–287) but this is the first report of conspecific predation by *B. canorus* tadpoles.

Submitted by **LAUREN M. CHAN**, Department of Ecology and Evolutionary Biology, Corson Hall, Cornell University, Ithaca, New York, 14850 USA; e-mail: lmc36@cornell.edu.

BUFO PARACNEMIS (NCN). **FEEDING BEHAVIOR.** On 13 April 1998 at 1915 h in the state of Goiás on the upper Tocantins River, Brazil, I observed gorging behavior in which *Bufo paracnemis* (7.76 cm SVL) consumed leaf-cutter ants (*Atta* sp.). The toad approached a line of ants that had used the same path every night for no fewer than 9 nights, traveling from their nest to a tree ca. 50 m away. The toad positioned itself ca. 15 cm from the line of ants and sat motionless for 10 min. An ant strayed from the main line, 5 cm from the toad, and was consumed, eliciting a strong feeding response in the toad. It proceeded to push itself up as high as its front arms would allow and peer at the main line of ants. It then returned to a normal resting position with most of its ventral surface in contact with the ground and oriented toward other stray ants. The toad never moved its position; it only changed its orientation occasionally to redirect its head toward a stray ant. During the next 3.2 h, the toad consumed 113 ants. On seven occasions, the first tongue strike failed to gather the ant and a second tongue strike was required. The last ant was consumed at 2251 h. Occasionally the largest of the worker ants approached the toad and actually climbed onto it. The ants appeared unable to recognize the toad as a threat and crawled off. Several of these walked in front of the toad while leaving and were eaten. On two occasions, ants carrying leaf material were consumed along with their vegetative cargo.

I thank Nelson Da Silva Jr., Catholic University of Goiás, FURNAS – Centrais Eletricas S.A. – Serra da Mesa Energia S.A., and Mark Wilkinson for funding and assistance in Brasil. I thank W. W. Lamar, Nelson Da Silva Jr., Jim O'Reilly, and Stephen Richter for critical review of the note.

BUFO VALLICEPS (Gulf Coast Toad). **DIET**. Campbell and Davis (1968. Herpetologica 24:327–328) studied the stomach contents of 21 adult *Bufo valliceps* and found the bulk of the food items were coleopterans and isopods. There are few other data published on the diet of this toad. Here we report additions to the diet of *B. valliceps*.

We examined the stomach contents of 36 *B. valliceps* (21 females, 13 males, and 2 juveniles) from Cedar Hill State Park, Dallas Co., Texas, USA. All were collected on park roads between 2030 and 2200 h from 19 May to 3 August 1999. The habitat at the study site is Tall Grass Prairie in middle stages of secondary succession with isolated patches of hackberry, *Celtis laevigata*, and mesquite, *Prosopis glandulosa*. Specimens were stomach flushed (Legler and Sullivan 1979. Herpetologica 35:107–110), and stomach contents were identified to Order. Table 1 summarizes these data.

TABLE 1. Prey consumed by *Bufo valliceps* (N = 36) from Cedar Hill State Park, Dallas County, Texas.

Diplopoda	1	0.57	1
Totals	176	100	36

A Simpson's diversity index was calculated for the stomach contents of each toad. Although it was expected that females (due to their larger size) would display a higher average diversity of prey items than males, a comparison of the indices revealed no significant difference between the sexes (independent t-test: $t = 0.057$; $p = 0.615$; $df = 32$; ns). The mean diversity of prey items for females was 0.323, and for males 0.248. No correlation could be established between diversity of stomach contents and body weight.

We thank Ardell Mitchell, Winston Card, and Carl J. Franklin for their comments on this manuscript. We would also like to thank the Texas Parks and Wildlife Department (permit # 51-98) and the staff of Cedar Hills State Park for their support.

CERATOPHRYS CRANWELLI (Cranwell's Horned Frog). **PREDATION**. Frogs of the leptodactylid subfamily Ceratophyinae (*Ceratophrys*, *Lepidobatrachus*, *Chacophrys*) are renowned for their aggressive predatory feeding behaviors. Whereas many different vertebrates have been cited as prey (e.g., young chickens by *C. ornata* and toads by *L. asper* [Budgett 1899. Q. J. Microsc. Sci. 42:75–77]; adult frogs by *C. cornuta* (Duellman 1978. Misc. Pub. Mus. Nat. Hist. Univ. Kansas No. 65]), most of these reports are anecdotal and descend from a few original observations in nature. Only recently have more rigorous reports of predation in nature begun to surface (e.g., frogs, reptiles, and mice by *C. cornuta* [Duellman and Lizana 1994. Herpetologica 50:51–64]; frogs by *Chacophrys pierotti* [Pueta and Perotti 1999. 5th CLAH 12–17 Dec 1999]).

Herein I report a natural instance of predation by *Ceratophrys cranwelli* on two other species of anurans. At 2130 h on 30 December 1999, an amplectant pair of *C. cranwelli* (UWSP 3595–96) were collected from an open, manmade lagoon within the city limits of Filadelfia, Departamento Boqueron, Paraguay (22°20.766'S, 60°01.760'W; 190 m). The two frogs were kept overnight in a plastic bag with water. At 1100 h the following morning eggs were found with the frogs. The frogs were then removed to a cloth bag. At 1900 h the following day two partially digested anurans were discovered in the bag. The remains were of a *Dermatonotus muelleri* and a *Physalaemus biligonigerus* (both specimens UWSP 3647). Both were extensively digested anteriorly, but decreasingly so posteriorly indicating anterior-first digestion and perhaps consumption. Identification of *D. muelleri* was possible by the remaining skin and skull, whereas that of *P. biligonigerus* was possible by the presence of keratinized spades on the hind feet, round black spots over the inguinal regions, and markings on the hind limbs. It is unknown if the two dead frogs came from the male (UWSP 3595), the female (UWSP 3596), or both. However, the breeding pair exhibited marked sexual dimorphism (UWSP 3595: SVL = 70.8 mm, Jaw Width = 43.5 mm; UWSP 3596: SVL = 93.0 mm, JW = 56.5 mm) and so it seems more likely that the two frogs came from the female. Comparison of interorbital diameter of the regurgitated specimen of *D. muelleri* (as it was one of the only remaining measurable features) of 5.2 mm, to that of two other specimens collected from Filadelfia (UWSP 3636: IOD = 4.9 mm, SVL = 56.5 mm; UWSP 3637: IOD 5.8 mm, SVL = 54.4 mm) suggests that it was an adult *D. muelleri*, likely >50 mm in length. The two specimens of *C. cranwelli* remain alive in the anuran research colony of the Department of Biology, University of Wisconsin-Stevens Point. Other specimens mentioned, including the regurgitated frogs, are deposited in the Division of Herpetology, Museum of Natural History, University of Wisconsin-Stevens Point, as will be the specimens of *C. cranwelli* upon their death.

Submitted by **ERIK R. WILD**, Department of Biology and Division of Herpetology, Museum of Natural History, University of Wisconsin-Stevens Point, Stevens Point, Wisconsin 54481-3897, USA (e-mail: ewild@uwsp.edu).

HYLA RANICEPS (NCN). **COMBAT**. *Hyla raniceps* has a wide distribution in Argentina, Bolivia, Brazil, French Guiana, and Paraguay (Frost 1985. Amphibian Species of the World. Allen Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. v + 732 pp.). Despite this, ecological data for this species are scarce (Lutz 1973. Brazilian Species of *Hyla*. Univ. Texas Press, Austin & London, 260 pp.). Herein we describe agonistic interactions among males of *Hyla raniceps* in a flooded area at the Lagoa Grande farm, 30 km from the municipality of Pontalina (17°31'23"S, 49°26'49"W; 642 m), State of Goiás, Central Brazil.

The observations took place during the nights of 7 Dec 1999 and 13 Jan 2000. On 7 Dec, we observed a male (A) *Hyla raniceps* begin to pursue another male (B) that was ca. 10 cm from A's perch on a bush. When A made physical contact with B, it jumped on B's back, grasped it in an axillary position, and tried to move it off the perch. Male B tried to escape from this embrace by kicking male A with it's hind legs. Both males began kicking each other as they vocalized (encounter call). The combat bout lasted for 20 seconds. After their separation, male (A) began to emit the advertisement call, and B was silent with it's vocal sac inflated. Later, it moved 8 m from the combat site.

On 13 Jan after the above observation, we introduced three males into the territory of a male calling (resident 1) from a bush. The resident male alternated between advertisement calls and territorial calls, moving towards the closest male invader. Soon after, it jumped on the back of the invader kicking it with it's hind legs, and trying unsuccessfully to push it off the branch. The combat lasted for 15 seconds. Another invader at a lower position began to pursue the resident male, jumping on him and managing to push him down into the water. The introduced male assumed the position of holder of the territory (now resident 2), emitting the advertisement call. This interaction lasted for 45 minutes. The experiment continued with the introduction of a new male at the site. This male settled down on a parallel branch, the same height as resident 2. Resident 2 emitted some isolated notes for ca 5 minutes, while the other male remained silent. After this period, resident 2 emitted the advertisement call. After 20 minutes in silence, the introduced male jumped into the water, climbed the bush, and remained silent for more than an hour, apparently adopting a satellite behavior.

In conclusion, the male-male combat in *Hyla raniceps* involved: 1) harassment, 2) embraces and kicks with the hind legs, and 3) possible adoption of a satellite behavior. The results show that combat among males for territory dispute exists in the mating system of *Hyla raniceps*, something that has not reported in this species (Lutz 1973, *op. cit.*.).

We thank J. P. Pombal, Jr. for critical reading of the manuscript. Eduardo L. Mesquita, Marcus Vinícius D. G. Parreira, Leonora A. dos Santos, and Henrique S. Costa helped with the fieldwork. RFJ and RPB were supported by fellowships from CNPq, and LDG was supported by a fellowship from CAPES. This research was supported by CNPq (process n. 400381-97.4).

LIMNONECTES MALESIANUS (Malesian Frog). **ECTOPARASITE**: *Limnonectes malesianus* is a moderate-sized (70–150 mm SVL) forest-dependant ranid frog, known from Borneo, Peninsular Malaysia, and Singapore (Inger and Tan 1996. Raffles Bull. Zool. 44[2]:551–574). During an amphibian survey on the night of 29 July 2000, at the Nee Soon Swamp Forest, Central Catchment Nature Reserve, Singapore, a pair of adult *L. malesianus* was observed in axillary amplexus at 2130 h. The male (125 mm SVL) was light brown, while the female (105 mm SVL) was reddish brown. Both were in the middle of a shallow (2.5 cm depth) stream. Water was slowly moving over sandy substrate with scattered detritus. At the moment of encounter, the male was observed to be releasing sperm accompanied with writhing movements of the vent. A number of unpigmented ova (ca. 30, 1.5 mm diameter) had already been deposited in loose clusters posterior to the amplectant pair. The pair was photographed and left undisturbed, but re-visited again an hour later, still at the same locality. This time, a pair of swamp leeches (*Hirudinaria* sp.) was observed swimming towards the amplexing *L. malesianus* with undulations of their dorso-ventrally compressed bodies. Both leeches attached themselves to the region of the left femur of the female frog. After five minutes, one leech was removed and collected, during which the amplexing pair separated. After half an hour, the remaining leech was also removed and collected. Both leeches are deposited at the Raffles Museum of Biodiversity Research Zoological Reference Collection (ZRC 2000.2501, 2502; relaxed lengths 71.5 and 67 mm). During preservation, viscous blood was regurgitated from the anterior sucker by ZRC 2000.2502, which was attached to the host for half an hour, while no blood meal was noticeable from ZRC 2000.2501, which was detached from host after only five minutes. This is a first account of leeches functioning as ectoparasites of this anuran species.

PHYLLOMEDUSA DISTINCTA (Leaf Frog). **TADPOLE PREDATION**. Field observations of predation on tadpoles are rare (Bolitho and Retallick 1996. Herpetol. Rev. 27:140–141). Among vertebrates, the predation exerted by fishes is important and well documented (e.g., Katz et al. 1988. Ecology 69:1865–1870). The importance of predation by other vertebrate predators remains little known, although kingfishers and turtles are potentially significant predators (Bolitho and Retallick, *op. cit.*; Heyer and Muedeking 1976. Washington Acad. Sci. 66:235–239).

Between February 1990 and September 1991 during monthly four-day trips, I made observations of tadpole predation by two previously unreported avian predators. These observations were made at a pond ca. 20 x 7 m at the Atlantic Forest Reserve of the Parque Estadual de Carlos Botelho (24°12'S, 47°55'W, 60 m elev.) Sete Barras, São Paulo, southeastern Brazil.

The green kingfisher, *Chloroceryle americana*, and the great kiskadee, *Pitangus sulphuratus*, were observed to feed on the tadpoles of *Phyllomedusa distincta*. The green kingfisher was observed to concentrate its foraging efforts on these tadpoles for long periods of time and was successful at capturing large numbers of tadpoles. Predation by the great kiskadee on tadpoles of other species has been documented previously (Crump and Vaira 1991. Herpetologica 47:316–321; Vaira and Coria 1994. Herpetol. Rev. 25:118).

I am grateful to the late A. J. Cardoso for guidance during my M.Sc. dissertation. I also thank C. F. B. Haddad, I. Sazima, A. Abe, and P. S. Oliveira for valuable suggestions, the Conselho Nacional de Desenvolvimento Científico e Tecnológico for financial support (proc. 130337/90-0), and the Instituto Florestal de São Paulo for permission to study in the Parque Estadual de Carlos Botelho.

RANA CURTIPES (Bicolored Frog). **DEATH FEIGNING**. Death feigning is reported in hylid frogs (Sazima 1974. J. Herpetol. 8:376–378), and in some bufonids (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.); Zamprogno et al. 1998. Herpetol. Rev. 29:96–97). However, this behavior is unreported for ranids. Herein, we report death feigning behavior in *Rana curtipes* from the western Ghats region in Karnataka, India (15°4'N, 74°33'E).

During May 1998 in western Ghats, we observed hundreds of newly metamorphosed *R. curtipes* (31–42 mm SVL, 1.4–5.5 g) on the bank of a stream. When the froglets were held in hand for observation, they exhibited a peculiar posture. They turned with their belly upwards, folded their limbs close to their body, and remained motionless. They remained in this position from 30 sec to 12 min, after which they tried to flee and often urinated. The frequency of this behavior was reduced with the growth of the froglets (47–50 mm SVL) and was rarely seen in laboratory-reared individuals 3–4 months after metamorphosis (58–60 mm SVL). This behavior has not been reported in the juvenile congeners *R. tigrina*, *R. cyanophlyctis*, *R. temporalis*, or in *Bufo melanostictus*.

TESTUDINES

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). **EARLY NESTING**. At 1130 h EDT 15 April 2000, a female *Kinosternon subrubrum* (carapace length, 110 mm) was found at the Mason Neck National Wildlife Refuge, Fairfax Co., Virginia, USA with its body elevated at an angle ca. 45° to the soil surface. We first thought the turtle was emerging from a hibernaculum; *K. s. subrubrum* commonly hibernates underground at Mason Neck, and normally emerges during April (Ernst et al. 1997. Bull. Maryland Herpetol. Soc. 33:1–62). The turtle's shell was clean with no soil adhering to it, as is normal when first emerging from

hibernation; but when the female was picked up, it was apparent that she was excavating a nest cavity with her hindlimbs, not emerging from a hibernaculum. The site was located in full sunlight near the edge of an old field ca. 1.8 m from open, mixed, hardwood-pine woods. The grass litter had been scraped clear, and the flask-shaped cavity had a ca. 10 mm deep x 15 mm wide neck leading to a larger ca. 20 mm deep x 25 mm wide chamber. The female was palped, but no oviductal eggs were detected. Mud turtles normally nest at Mason Neck from 29 May to 22 June (Gotte 1988. Master's thesis. George Mason Univ., Fairfaix. 135 pp.). Richmond (1945. Copeia 1945:217–219) reported nesting on 31 March in southern Virginia, but nesting in April must be considered rare farther north. Normally, female *K. subrubrum* undergo secondary vitellogenesis in March and April before preparing their follicles for ovulation in May and June (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C.).

Submitted by **CARL H. ERNST**, **TERRY R. CREQUE**, and **KERRY A. HANSKNECHT**, Department of Biology, George Mason University, Fairfax, Virginia 22030-4444, USA (e-mail: CErnst@gmu.edu).

LEPIDOCHELYS OLIVACEA (Olive Ridley Sea Turtle) **PREDATION**. Endangered *Lepidochelys olivacea*, *Chelonia mydas agassizi*, and *Dermochelys coriacea* nest on Playa Naranjo, Santa Rosa National Park, Costa Rica (10°45'N, 85°40'W). During our daily and nocturnal investigation of marine turtle activity on the beach between October 1998 and March 1999, we encountered 16 dead adult female *L. olivacea* killed by coyotes in October (3), November (4), December (0), January (5), and February (4). It was evident that the dead turtles had not merely washed up onto the beach and been scavenged by the coyotes because the turtles were attacked mid-crawl prior to or after completion of the nesting process. Injuries inflicted by the coyotes ranged from the removal of large portions of tissue from the neck area to complete disembowelment. We encountered four additional dead *L. olivacea* adults on the beach during our investigation, which we did not attribute to coyote predation, because the turtles showed no obvious external injuries. Coyotes are a well-known and common predator of olive ridley nests at this site, consuming 74% (159 of 215) of the *in situ L. olivacea* nests recorded during our study. However, Cornelius and Robinson encountered no signs of predation on adult *L. olivacea* by coyotes during their studies in 1971–2 and 1983–4 (S. Cornelius, pers. comm.). It appears that only within the past 15 years have coyotes at Playa Naranjo learned to consume adult *L. olivacea* coming ashore to nest.

LACERTILIA

LEIOCEPHALUS CARINATUS VIRESCENS (Exuma Islands Curlytail Lizard). **INTERSPECIFIC AGGRESSION**. Despite its conspicuous nature and widespread occurrence throughout the Exuma Island chain, Bahamas, very little is known about the ecology and behavior of *Leiocephalus carinatus virescens*. Generally, adult male *Leiocephalus* are known to be highly territorial and often react aggressively toward conspecifics (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. Univ. Florida Press, Gainesville, Florida. 720 pp.). Herein I report an incident of aggressive behavior by an adult male *Leiocephalus* toward an avian species.

On 6 March 1998 at 1100 h, I witnessed two separate acts of aggression between an adult male *L. c. virescens* (ca. 9 cm snout-vent-length) and two Bahamas mockingbirds (*Mimus gundlachii*). The observations occurred on Alligator Cay, Exuma Cays Land and Sea Park, Bahamas (24°23'N, 76°38'W), in shallow dry leaf litter under a sparse, 3 m canopy of narrow-leaf blolly (*Guapira discolor*). The aggressive episodes occurred in the territory of a male *L. c. virescens* and involved the resident, two adult male conspecific intruders, and two Bahamas mockingbirds (ca. 22 cm total length). I observed all aggressive behaviors from a distance of 4 m and my presence appeared to have no effect on the animals involved. The first encounter was between an equal-sized male conspecific that entered the territory of the resident male and approached to within 1 m. The intrusion initiated stereotypical bobbing displays and symmetrical tail coiling (Evans 1953. Copeia 1953:50–54) from the resident male towards the intruder. With tails curled, both males oscillated between bobbing and remaining stationary for ca. 20 seconds, after which the resident male charged the intruder, causing it to flee from the territory and across the leaf litter. Immediately following this incident, a Bahamas mockingbird, perhaps attracted by the commotion, approached the resident lizard from the ground. The presence of the bird caused the resident curlytail to coil its tail but not to perform bobbing displays. When the mockingbird approached to within 1 m of the resident, the curlytail charged the bird causing it to hop away. After ca. 30 seconds, a second, but smaller, adult male *L. c. virescens* entered the same territory and approached the resident curlytail to within 0.7 m. Again, the behavior of these two curlytails oscillated between bobbing and stationary displays while both tails remained curled. Within 30 seconds, the resident charged this second intruder causing it to flee. Immediately following the incident, a second mockingbird was attracted to the commotion and approached the resident curlytail from the ground. Similar to the first encounter, the resident remained motionless with a curled tail until the mockingbird approached to within 0.8 m. Without displaying, the curlytail charged and lunged with an open mouth at the mockingbird, causing it to fly away in retreat.

The frequency of interactions between curlytails and mockingbirds is unknown. It may be that the succession of interactions with other male lizards led to unusually high hormone levels in the focal lizard, and that high hormone levels prompted an unusual aggressive response toward the mockingbirds. Alternatively, aggression between curlytails and mockingbirds may be a routine feature of the natural history of both species.

SERPENTES

ELAPHE PORPHYRACEA LATICINCTA (Malayan Red Mountain Racer). **DIET**. *Elaphe porphyracea laticincta* (*sensu* Schulz and Helfenberger 1998. Sauria 20[1]:25-45) is a subspecies found in the montane regions of Peninsular Malaysia and Sumatra. This species has been known to prey on small mammals such as mice and shrews (David and Vogel 1996. The Snakes of Sumatra – An Annotated Checklist and Key with Natural History Notes. Edition Chimaira, Frankfurt am Maim. 260 pp.). On 25 June 2000 in Cameron Highlands, Pahang, Peninsular Malaysia, a recently road-killed adult specimen was found by one of us (AHBL). It was found amidst tea plantations (elevation 1600 m) on the lower slopes of Gunong Brinchang. It still retained a deep brick-red color. The stomach contents were partially extruded, revealing a partially digested small mammal. Other than fur, mandibular bones, and skeletal parts of a forelimb, only the posterior half of the mammal remained. Upon closer inspection, the prey was identified to be a short-tailed mole (*Talpa micrura*), based on the presence of its characteristic enlarged fore-limb/digging claws. This is the first account of *E. p. laticincta* preying on *T. micrura*. Both specimens are deposited at the Raffles Museum of Biodiversity Research Zoological Reference Collection (*E. p. laticincta*: ZRC.2.4777, SVL 776 mm, tail 114 mm; *T. micrura*: ZRC.4.8102, hind foot 15.8 mm, tail 4.4 mm).

ELAPHE VULPINA (Fox Snake). **WINTER ACTIVITY and NATURAL DISTURBANCE DURING HIBERNATION**. Winter surface activity at low temperatures by snakes that are normally in hibernation in higher temperate latitudes is rare, and the cause of such unusual behavior is often difficult to discern (see Brown and Brown. 1995. Herpetol. Rev. 26:134–135). This account reports an instance of such activity and a likely reason for it.

On 18 February 2000 one of us (DJB) observed a fox snake active on fresh snow in subfreezing temperatures during the worst snowstorm of the winter in northwestern Illinois. The snake (INHS 15631) was an adult female (735 mm body length, 828 mm total length, 194 g live mass) and was collected on a gravel road at 1515 h at the following locality: USA: Illinois, Mercer Co., Greene Twp., ca. 4 km (linear) NE Viola, 3 km E of Rt. 67 on rural road 1150 N, 41°13'54"N, 90°33'18"W, elevation 240 m. The roadsides consisted of mowed grass sloping to a pasture on the south and unmowed grass sloping upward and bordering a weedy, "set-aside" field on the north.

When discovered during conditions of heavy, drifting snow, the snake was orientated longitudinally in the center of the road on the surface of 18–20 cm of fresh snow and was in a weak, nearly linear, serpentine shape. There was a shallow trail ca. 20 cm long in the snow behind it. The snake was observed for 5 min. and during this time, it moved very lethargically and slowly (ca. 1 cm/min), and appeared disorientated. It also appeared to be searching for a scent, as its tongue flicks were frequent (unmeasured) but very slow, each lasting 4–5 sec. When picked up by hand, it slowly opened its mouth and moved very little. The temperature range that day at the National Weather Service station in Moline, Illinois, ca. 25 km NE of the locality, was –4.4°C to –0.5°C, and the mean daily temperature was –2.2°C. The snake was left outside after being collected and died within several hours.

Brown and Brown (*op. cit.*) reported winter activity by an adult *Elaphe vulpina* on 17 February 1991, on an ice pond in McLean Co. in central Illinois at warmer ambient air temperatures (9.4°C). They hypothesized that warm daily temperatures during the preceding period and/or local disturbance at the pond that day may have been responsible for this snake's activity.

The activity of the fox snake reported here did not involve natural emergence related to early, unseasonably high temperatures. In addition to the subfreezing temperatures on 18 February that were subsequently fatal to the snake, the mean daily temperature (–0.9°C) and the means of daily minimum and maximum temperatures (–4.5°C and 2.8°C) at Moline, Illinois during the preceding five-day period were also low. Road activity by fox snakes is seldom observed before mid-April in this region of Illinois, as recorded in an ongoing, long-term survey of snake activity by one of us (ALM). More importantly, there is little correlation between short-term local temperatures on the surface and early emergence from hibernation by snakes (Gibbons and Semlitsch. 1987. *In* Seigel et al. [eds.], Snakes, Ecology and Evolutionary Biology, pp. 396–421. McGraw-Hill, Inc., New York).

Rather than a thermal response, there is evidence that the snake was active on the surface because of a noxious encounter with a small mammal in its hibernaculum. That the snake was underground was evident from traces of mud on several areas of its body, and postmortem examination revealed several small injuries on its head that were likely caused by bites. These injuries bled slightly during examination, indicating that they were relatively fresh. The most conspicuous was a ragged tear (4.5 mm long) of the left parietal scale, extending obliquely from the anterior medial parietal line postero-ventrally to the upper temporal area, where the musculature was lacerated to the depth of the supratemporal bone. Corresponding to this laceration were 3 distinct and one indistinct shallow grooves, ca. 0.4 mm wide and 1.2 mm long, on the dorsal surface of the parietal bone, which was not penetrated or fractured. The left cornea had a small perforation in the lower half; and the left lower postocular, a puncture wound ca. 1.2 mm long and 1 mm deep. In the snout region, the left posterior nasal scale had a laceration causing a detachment of a portion of this scale from the underlying tissue; the lower right portion of the rostral scale had a similar laceration. Linear distance between the parietal-temporal/ocular area wounds was 6.3 mm; and between rostral/nasal wounds, 6.6 mm. In addition, the mouth had traces of blood and soil between the tooth rows, suggesting

that the snake recently opened its mouth underground because snow covered the soil surface.

It is likely that a small mammal, possibly a rodent or shrew, encountered and bit the snake, which caused it to be driven from the hibernaculum to the surface. Snakes are known to move about in their hibernacula at relatively low temperatures and respond to various stimuli during hibernation (see Sexton and Hunt. 1980. Herpetologica 36:20–26). The hibernaculum used by the snake reported here was not obvious from a subsequent search of the roadsides after snowmelt, but *Elaphe vulpina* is known to use mammal burrows among other microhabitats (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason Univ. Press, Fairfax, Virginia. 282 pp.). Ground squirrels (Rodentia: *Spermophilus tridecemlineatus*) and their burrows are common along roadsides in this area, and fox snakes have been previously observed in the vicinity of such burrows in the spring by one of us (ALM) in adjacent Henry Co., Illinois. The wounds and distances between them were consistent with the snake being bitten in two areas of the head, anteriorly (rostral/postnasal wounds) and posteriorly (parietal-temporal/ocular area wounds) by small upper and lower incisor teeth. The tear of the left parietal scale and the corresponding grooves on the bone below suggest that the mammal was trying to pull off some flesh. Also consistent with a prior noxious encounter is that the specimen opened its mouth when picked up by hand, defensive behavior that we and others (Ernst and Barbour, *op.cit.*) have observed as very unusual in most individuals of this species. The pattern of wounds and circumstances in which the snake was discovered were inconsistent with injuries that would result from a human cause; there was no evidence of human activity in the immediate area or of fresh tire tracks in the snow on the road. Also, the weather conditions and the mud on the snake's body and inside its mouth suggest that an encounter with a small mammal on the surface was unlikely.

The wounds probably would not have been fatal to the snake, but the weather conditions were. The frequency and broader ecological implications of encounters between mammals and hibernating snakes are unknown. Using circumstantial evidence near hibernacula in the spring and fall, Fitch (1999. A Kansas Snake Community: Composition and Changes Over 50 Years. Krieger Publ. Co., Malabar, Florida. 165 pp.) hypothesized that predation upon hibernating snakes by small mammals such as mice and shrews may be somewhat common in years of low resource availability and may represent a significant source of mortality in snake populations.

EUNECTES MURINUS (Green Anaconda). **ESCAPE BEHAVIOR and RESPIRATION**. Documented information about the escape behavior of *Eunectes murinus* is scarce. Often it is simply mentioned that this species takes to water to escape predators or other dangers, and remains submerged for extended periods of time. Furthermore, to our knowledge, there are no reports of *E. murinus* burrowing into mud to elude predators. However, during dry seasons, individuals of *E. murinus* burrow into mud to avoid desiccation (Lopez 1984. Fauna Legendaria. Editorial Arte, Caracas; Rivas and Muñoz 1992. unpubl. report; Thorbjarnarson 1995. Americas 47:38–45). In addition, there is little substantiated data concerning the length of time *E. murinus* can refrain from breathing, whether it be while feeding underwater (Mole and Urich 1894. Proc. Zool. Soc. Lond. 1894:505–506; Wehekind 1955. Brit. J. Herpetol. 2:9–13) or when submerged to avoid predators. At best, anecdotal generalizations indicate that this species can suspend respiration for relatively long periods of time. Some reptile species can revert to anaerobic metabolism during times of high-energy demands, such as diving by aquatic reptiles (Bennett 1982. *In* C. Gans and F. H. Pough [eds.], Biology of the Reptilia, Vol. 13, Physiology D, pp. 155–199. Academic Press, London, UK; Seymour 1982. *In* C. Gans and F. H. Pough [eds.], Biology of the Reptilia, Vol. 13, Physiology D, pp. 1–51. Academic Press, London, UK); but overall this physiological activity is not thoroughly understood, and we are unaware of it being studied in *E. murinus*. Herein we report a case of an *E. murinus* burrowing into mud to avoid capture, and subsequently refraining from breathing for an extended period of time, possibly aided by anaerobic metabolism.

On 25 January 2000, a group of 18 people assembled at Quito, Ecuador, to be part of an expedition to search for a large *E. murinus* that had reportedly been seen in the Cuyabeno Wildlife Reserve, Sucumbios Province, Ecuador. The Cuyabeno Wildlife Reserve (ca. 600,000 ha) lies in the Amazon Basin at an elevation of less than 300 m, and straddles the equator (extending from ca. 75°–76°W longitude). Within the Reserve is an elaborate network of rivers, lakes, lagoons, and flooded forest that are markedly affected by seasonal rains. For about nine months out of the year the area

FIG. 1. Team members attempting to extricate a female *E. murinus* (TL = 4.76 m) from soft mud into which it was burrowing. (Photo by Jean-Thomas Bujard)

endures a wet season, with a dry season that extends roughly from December through February. Our fieldwork was performed well into the dry season, so the lakes and rivers in the area were essentially at their lowest levels. As a result, some of the areas we worked in were not covered with water but were extremely muddy.

On 27 January 2000, two team members located an adult, female *E. murinus* (TL = 4.76 m) inside a hollowed out, fallen tree in the exposed muddy bed of Laguna Grande. The specimen was located at 1300h during which the air temperature was 34°C, temperature inside the tree was 27°C, and the snake's external body temperature was 29°C. We believe this *E. murinus* took shelter in the log to avoid the high daytime temperatures associated with the dry season and to wait for the lake's water level to rise during the ensuing wet season. Attempts to remove the *E. murinus* from its lair failed, though it did eventually come out on its own and partially buried itself in the mud, under the root system of the upturned tree. Efforts were made to expose and extricate the *E. murinus* by pulling off sections of the tree's root structure. As this occurred, the specimen started to burrow, almost vertically at times, into the soft mud to escape capture (Fig. 1.). We estimate that the anterior portion of this *E. murinus* reached a depth of ca. 60 cm. The more team members worked to uncover this specimen, the more it burrowed into the mud, until eventually ca. 1.5–2.0 m of its body was buried. As we continued to pull pieces of the root system away and dig out some of the mud, it became clear that the *E. murinus* was not able to breathe, as there were no air pockets in the mud. This became particularly evident when we saw water seeping out from the hole where the *E. murinus* had burrowed.

Eventually we retrieved the specimen (Fig. 2), though it took an appreciable amount of time and effort. We estimate that this *E. murinus* suspended respiration for a period of ca. 40–45 min. This is particularly interesting because the specimen was struggling against the efforts of its captors, which we feel would have resulted in an increased metabolic rate and subsequent tissue oxygen demand. Under these conditions, some reptiles are known to resort to anaerobic metabolism (Bennett and Dawson 1976. *In* C. Gans and W. R. Dawson [eds.], Biology of the Reptilia, Vol. 5, Physiology A, pp. 27–223), and it seems probable that *E. murinus* utilized anaerobiosis while it was submerged in the mud. Furthermore, the *E. murinus* was nearly exhausted from its struggle (i.e., the specimen exhibited no aggression or resistance to handling once captured), which has been reported to be a symptom of reptiles that have utilized anaerobic metabolism (Bennett 1982. *In* C. Gans and F. H. Pough [eds.], Biology of the Reptilia, Vol. 13, Physiology D, pp 155–199. Academic Press, London, UK).

Following capture, we allowed the *E. murinus* to rest for a short period, and then various measurements were made and its general health was assessed (e.g., body weight, presence of ectoparasites and injuries, etc.). When data collection was complete, the specimen was released.

Because *E. murinus* is a species highly adapted to a semi-aquatic existence, it is reasonable to conclude that the ability to suspend respiration for extended periods of time or use anaerobic metabolism would give *E. murinus* an advantage in both predatory and threat-avoidance activities. Since the actual anaerobic capacity of large reptiles is not well understood, well-documented field observations can be an important step in the study of this physiological process.

FIG. 2. Female *E. murinus* after being extricated from mud into which it had burrowed. The specimen was exhausted after the struggle and offered no resistance. (Photo by Jean-Thomas Bujard)

We thank the members of the expedition team for their help and support with regard to the capture and study of the specimen. Bill Cacciolfi (New World Expeditions, Springboro, Ohio), Rudolph Runge (RungeTV, Cologne, Germany), Rudolf Bermel (Mediguard, Bonn, Germany) and Continental Airlines are acknowledged for providing financial and/or other support. Thanks to Jane Strimple, Ritt Enderson, Bill Cacciolfi, and Jean-Thomas Bujard for reviewing the manuscript, and to Frederick Frye for his input on reptile metabolism.

EUNECTES MURINUS (Green Anaconda). **JUVENILE PREDATION**. Larger-sized reptiles tend to suffer little from predation, whereas juveniles typically are more exposed to predators and suffer higher mortality rates in their first years. This observation is typical among female green anacondas (Rivas 1999. Ph.D. dissertation. Univ. Tennessee, Knoxville, 287 pp.). However, smaller adult males risk predation by spectacled caimans (*Caiman crocodilus*; Rivas et al. 1999. Herpetol. Rev. 30:101) and by larger female anacondas (Rivas and Owens 2000. Herpetol. Rev. 31:45–46). In this contribution we document predation on juveniles of different sizes. These observations were made in the Venezuelan llanos, Distrito Muñoz, Apure State (7°30'N, 69°18'W).

On 25 April 1995 we observed a female anaconda (187 cm TL; 3.25 kg) being harassed by a crab-eating fox (*Cerdocyon thous*). The snake was on dry land and had adopted a defensive position. The fox repeatedly tried to grab it, but jerked back each time as the snake snapped defensively. We interrupted the interaction and caught the snake, which had numerous ticks (evidence of having been on dry land for a while). If we had not interrupted the fox, the snake probably would have been eaten because she may have become exhausted in a short time and, not having any water nearby, was not likely to have escaped.

On 15 January 1996 we saw a tegu lizard (*Tupinambis teguixin*) carrying a neonate-size anaconda in its mouth. The snake did not have any bite marks or external evidence of having been killed by the tegu, so it was not possible for us to assess whether the tegu killed it or had found it dead. However, because tegus are generalist foragers and often forage near the water, they are likely predators of neonates.

We implanted transmitters in four neonate green anacondas to study habitat use on 9 January 1996. Two of them were found dead on 12 February. We found one of the transmitters at the bottom of a tree that held an active nest of crested caracaras (*Polyborus plancus*: Falconidae). The other transmitter was found among some bushes with the antenna chewed up, but with no other hint regarding identity of the predator. The other two animals were alive at the end of the three-month-long follow-up, but no information on their later survival is available.

The animals reported in this contribution as preying on juvenile anacondas are fairly common in the llanos. This suggests that risk of predation may be an important selection pressure leading to fast growth in juveniles.

We thank The World Conservation Society, The National Geographic Society, and The Wildlife Conservation Society Field Veterinary Program for logistic support. We thank COVEGAN for allowing us to work on their land. We also thank W. Karesh, J. Thorbjarnarson, C. Molina, and M. Muñoz for help in the field work.

MASTICOPHIS FLAGELLUM (Western Coachwhip). **DIET.** *Masticophis flagellum* is known to feed on a large variety of food items including insects, lizards, snakes, small turtles, birds, and small mammals (Guidry 1953. Herpetologica 9:49–56; Hamilton and Pollack 1956. Ecology 37:519–526; Collins 1974. Univ. Kansas Publ. Mus. Natur. Hist. Publ. Ed. Ser. 1:1–283). Here we report two food items found in the stomach of a *M. flagellum*. On 17 April 1999 at 2230 h, an adult male *M. flagellum* (1186 mm total length, 217 g) was found DOR on US 385 twenty-two miles south of Fort Stockton in Pecos Co., Texas, USA. The stomach of the snake was fully distended indicating recently-eaten prey. An adult *Cnemidophorus marmoratus* (289.1 mm total length, 23.7 g) was palped from the snake. A grasshopper (Orthoptera) was also found in the stomach of the snake. To our knowledge, this is the first report of *C. marmoratus* in the diet of *M. flagellum*. All three specimens were preserved and placed at the University of Texas at Arlington Collection of Vertebrates (*M. flagellum* UTA-R46048, *C. marmoratus* UTA-R46049).

We thank Ardell Mitchell, Winston Card, and Carl J. Franklin for their helpful comments on this manuscript, and the staff of the Dallas Zoo Department of Herpetology for their support.

NERODIA FASCIATA (Southern Water Snake). **REPRODUCTION.** *Nerodia fasciata* normally reproduces from June through August with a typical litter size ranging from 9 to 50 (Wright and Wright 1957. Handbook of Snakes of the United States. Comstock, Ithaca, New York. 1105 pp.), but averaging near 15 (Tennant 1997. A Field Guide to Snakes of Florida. Gulf Pub. Co., Houston, Texas. 257 pp.). Herein we report on reproduction in two female *N. fasciata* that exhibited a phenology and fecundity consistent with these values.

On 9 July 1998 at 2240 h, an adult female *N. fasciata* (710 mm SVL, 220 mm tail length) was found on a floating mat of vegetation near the bank of an artificial pond at White Oak Plantation, Nassau Co., Florida, USA (Sec. 43, T4N, R26E). The observation occurred following the second major rain event of the summer. The female was placed in a cloth bag, and retained overnight for measurements. The following day, we discovered that the female had expelled 34 neonates into the cloth bag. Thirteen individuals from this litter were found dead and subsequently were deposited in the Florida Museum of Natural History (UF116347–59). SVL for live young (mean ± SD, 163.5 ± 5.1 mm) and dead young (165.0 ± 3.3 mm) did not differ (t-test, $t = 0.93$, $P = 0.36$). Pooled measurements for all offspring were as follows: SVL 164.1 ± 4.5 mm (range 149.0–172.0 mm); tail length 65.4 ± 3.6 mm (59.0–72.0 mm); mass 5.3 ± 0.5 g (4.2–6.1 g). Although the initial mass of the female was not taken, its post-partum weight was 485.0 g. Live neonates and the adult female were later released at the capture location.

On 22 July at 1235 h, a second female was observed expelling offspring onto the muddy substrate along the shoreline of a small pond at White Oak Plantation; a significant rainfall event also occurred prior to this observation. Temperatures recorded at the time of the observation were 28.4°C substrate, 30.6°C water, and 31.3°C air at 2 m in the shade. Although the adult escaped, five neonates were captured for measurements. Measurements of the young were as follows: SVL 168.6 ± 2.7 mm (range 166–173 mm); tail length 59.2 ± 1.5 mm (57–61 mm); mass 4.7 ± 0.2 g (4.5–4.9 g). The captured neonates were released at the capture location except for one, which we deposited in the Florida Museum of Natural History (UF116360).

We gratefully acknowledge the entire staff of White Oak Conservation Center for funding and use of on-site facilities, Pat Ryder for expertise, and Kenneth L. Krysko and Steve A. Johnson for constructive comments.

PITUOPHIS MELANOLEUCUS MUGITUS (Florida Pine Snake). **DIGGING BEHAVIOR**. Adult Florida pine snakes (3 males, 3 females) were radio-tracked for periods of 6–26 months in sandhill habitats at the Katharine Ordway Preserve-Swisher Memorial Sanctuary, Putnam County, Florida, USA. During this period, three tagged males (132.5, 139.7, 142.0 cm SVL) were observed on nine occasions in the act of excavating pocket gopher (*Geomys pinetis*) mounds (Fig. 1). None of the tagged females (129.0, 142.8, 144.5 cm SVL) were found pursuing this activity.

Excavating snakes were successful on eight occasions in removing sand plugs placed by pocket gophers in exit burrows inside the mounds. These plugs probably serve to exclude predators and regulate air flow in burrow systems. Opening these plugs allow pine snakes an access point into the burrow system. On one occasion, a snake prematurely left the excavation site prior to clearing the exit plug, as a direct consequence of my presence. On a second occasion, another snake similarly left a mound following disturbance, but later returned after my departure, and finished the excavation. This snake was located the next morning (0530 h) inside the burrow, positioned about 1.5 m from the snake's access hole.

Snakes were encountered in the process of excavating mounds at 0800 (continuing until 0920), 0845, 0900, 0905 (continuing until 1000), 0920, 1045, 1055, 1145, and 1700 h (EST) in June (2), August (2), September (1), October (2), and November (2). Work at two excavations lasted ca. 55 and 80 minutes following the initial discovery. Both snakes completed excavations and entered burrow systems. The length of time required for snakes to complete an excavation is unknown, since most were encountered after they already had begun work.

Types of disturbances at freshly excavated mounds include scrapings 12–18 cm wide, conical depressions that conform to the shape of the snake's face, and impressions of dorsal and ventral scales. The final access hole is about the diameter of the excavating snake. Except for the holes, most of the marks quickly erode as the sand dries, making interpretation more difficult. However, once researchers see enough of these features, they should be able to distinguish them from other disturbances, which might prove useful as a survey technique for this species.

All of the excavating snakes were observed to use the "spading and scooping" actions, reported by Carpenter (1982. J. Herpetol. 16:394–401) for captive Oklahoma-caught bullsnakes. Carpenter found this behavior in adults of both sexes and in a juvenile, suggesting that this behavior might function in obtaining food or digging nests or retreats. He reported that bullsnakes responded positively to soil from pocket gopher mounds. Based on these observations, I suggest that Ordway pine snakes may have been using rodent odors as cues to accurately locate and dig out the mound plugs.

FIG. 1. Florida pine snake excavating a pocket gopher mound.

Pocket gopher tunnel systems commonly are used by Florida pine snakes as retreats, based on available telemetric data from the Ordway Preserve. These tunnel systems presumably provide safe havens from predators, fires, and adverse weather conditions and may serve as a source for food, particularly in light of Allen and Neill's report (1952. Florida Wildlife March:18–19), which states "...in many areas the pine snakes eat nothing but pocket-gophers, and spend most of their lives down the burrows of these rodents." Neill (1947. Herpetologica 4:29–30) also noted finding a large pocket gopher in the stomach of one pine snake and the remains of others in four other snakes.

I thank John F. Eisenberg and the Ordway board for permission to work on the Katharine Ordway Preserve-Swisher Memorial Sanctuary and for financial support to purchase the transmitters; Melvin Sunquist, for technical support; Steve A. Johnson for reviewing the manuscript; and Shelley E. Franz and others who helped track radio-tagged snakes.

PITUOPHIS MELANOLEUCUS SAYI (Bullsnake). **DIET**. Between 1988 and 1992, at the Crescent Lake National Wildlife Refuge, Garden Co., Nebraska, USA, 476 bullsnakes were captured by refuge personnel as part of a predator control program, and made available to us for dissection. Only 19.5% of the snakes (N = 93) contained food items (Table 1), with females (29.5%) more likely than males (15.2%) to contain food (Chi-square = 9.1, P = 0.003). Of the snakes with food, almost 90% had recently eaten mammals (mainly voles, *Microtus ochrogaster* or *M. pennsylvanicus*). Although birds or their eggs were found in 20% of the snakes, three times as many males as females contained avian food items (Chi square = 4.9, P = 0.027). This may reflect the greater movements (and therefore greater likelihood of encountering birds nests) made by males (Iverson, unpublished; see also Burger and Zappalorti 1988. Herpetologica 44:48–55). We found only one food type in most snakes, but two did contain two types (a duck egg and a vole in one snake, and a vole and kangaroo rat in another). Gut content data collected on the same refuge in 1938–1942 (Imler 1945. J. Wildlife Mgmt. 9:265–273) also revealed that voles were the principal food item (36% by volume), but that birds (including eggs) and mammals were nearly equally represented in the diet at that time (48 vs. 52% by volume, respectively). It is likely that this apparent drop in bird/egg predation is due to overall reductions in the waterfowl populations since the early 1940's, and to increases in small mammal populations (because of predator removal and reduced grazing/haying in the meadows). These data also confirm that the diet of the closely related gopher snake (*P. catenifer*; Rodríguez-Robles 1998. Copeia

Table 1. Food items recovered from guts (stomachs and intestines) of 93 bullsnakes from Crescent Lake Refuge (1988–1992). Totals of percentages are greater than 100 since some snakes had multiple prey items in their guts.

Food item	Females (N = 43)	Males (N = 50)	Total (N = 93)
Any mammals	40 (93%)	40 (80%)	80 (86%)
Voles (*Microtus*)	21 (49%)	22 (44%)	43 (46%)
Kangaroo rats (*Dipodomys*)	2 (5%)	3 (6%)	5 (5%)
Field mice (*Peromyscus*)	1 (2%)	1 (2%)	2 (2%)
Pocket mice (*Perognathus*)	2 (5%)	0	2 (2%)
Pocket gophers (*Geomys*)	2 (5%)	0	2 (2%)
Cottontail rabbits (*Silvilagus*)	1 (2%)	0	1 (1%)
Unidentified mammals	14 (33%)	14 (28%)	28 (30%)
Any birds	4 (9%)	15 (30%)	19 (20%)
Eggs	4 (9%)	13 (26%)	17 (18%)
Nestling pheasant	0	1 (2%)	1 (1%)
Nestling duck	0	1 (2%)	1 (1%)

1998:463–466) is much more diverse than that of the bullsnake. The only potential record of non-endotherm prey for the bullsnake is a brief mention of "insects" by Wright and Wright (1957. Handbook of Snakes. Comstock Publ. Assoc., Ithaca, New York. 640 pp.); however, they provide no further details.

THAMNOPHIS SCALARIS (Mexican Alpine Blotched Garter Snake). **LITTER SIZE**. On 8 June 1999, a pregnant female *Thamnophis scalaris* (37.0 cm SVL, 8.5 cm tail length (TL), 137 ventral scales), was found in Acambay, state of Mexico (19°56'N, 99°50'W), 17 km N of Toluca, Mexico. Eight offspring were born on 18 June 1999. Each neonate was measured, weighed, and ventral scales were counted. The female and neonates were released six days after parturition. The female's mass before and after parturition was 36.09 g and 23.18 g, respectively. The measurements of the neonates were (mean ± SD, range): 12.95 ± 0.61 cm, 12.0–13.9 cm SVL; 3.77 ± 0.40 cm, 3.1–4.2 cm TL; 1.24 ± 0.07 g, 1.12–1.35 g mass; 130.5 ± 7.65, 122–144 ventral scales. Only four litters of *T. scalaris* have been previously reported. Ramrez-Bautista et al. (1995. Herpetol. Rev. 26:12–13) reported litters sizes of 14 and 16 from two autopsied females. Rossman et al. (1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 256 pp.) reported litter sizes of eight and 15, with total lengths ranging between 16.8 and 18.1, and birth dates of 18 May and 30 May, respectively.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **COURTSHIP BEHAVIOR**. Male snakes have been shown to track females using predominantly chemical trailing (reviewed in Halpern 1992. *In* Gans and Crews [eds.], Biology of the Reptilia, Vol. 18, pp. 423–523. University of Chicago Press, Chicago, Illinois). Vision has also been shown to be important in semi-natural studies of the courtship behavior of the checkered garter snake, *Thamnophis marcianus* (Perry-Richardson et al. 1990. J. Herpetol. 24:76–78). Here, I report the use of vision by a male *T. s. sirtalis* for localizing a female for courtship in the field. An adult male *T. s. sirtalis*, 30 cm SVL, was observed from 1500–1600 h on 15 April 2000 (23°C, sunny) at Mendon Ponds County Park, Monroe County, New York, USA. This individual was moving through leaf litter on the forest floor, exhibiting rapid tongue flicking and directed movement. After making several loops over 20 min., the individual flushed out a female *T. s. sirtalis* (ca. 45 cm SVL) from under leaf litter. The male proceeded to pursue the female, actively chin rubbing along her back and tongue flicking continuously. After the initial activity, the female managed to move out of view from the male and freeze. At this point, the male raised the rostral third of his body off the ground and began moving his head from side to side, apparently looking for the female. As soon as the female moved, the male pursued her again, repeating the courtship behavior. This series of events (male courtship, female evasion, and male visual tracking) occurred three times over 20 min. Finally, the female evaded the male, who did not locate her after 20 min. of visual and chemical searching in the wrong direction. These observations suggest that male garter snakes will use visual localization to find females after first locating them chemically.

I thank Neil Ford for helpful comments for this note.

Erratum

A note concerning nocturnal climbing activity in two species of *Plethodon* (Trauth et al. 2000. Herpetol. Rev. 31:232–233) was inadvertently published again in HR 32:32. Proper citations of this paper should reference its first appearance.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section coeditor (addresses on inside front cover): J. Brian Hauge (lizards, amphisbaenians, crocodilians, *Sphenodon*); Charles W. Painter (amphibians); or Brian Butterfield (snakes, turtles). Authors are requested to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother (2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. Herpetol. Circ. 29:1–82); for Mexico as it appears in Liner (1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herpetol. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

PLETHODON CADDOENSIS (Caddo Mountain Salamander) and ***PLETHODON SERRATUS*** (Southern Redback Salamander). **NOCTURNAL CLIMBING ACTIVITY**. Nocturnal surface activity in the plethodontid salamander genus *Plethodon* has been well documented for a variety of species (Spotila 1972. Ecology 42:95–125; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.). Observations on the nocturnal climbing abilities of some members within this genus as well as in other plethodontids, however, have appeared less frequently in the literature (Cliburn and Porter 1986. J. Mississippi Acad. Sci. 31:91–96; Jaeger 1978. Copeia 1978:686–691). Herein, we report on nocturnal and climbing activity in two plethodontid species taken from the same study site.

On the evening of 14 April 2000 between 2030–2130 h, a group of 14 observers visited an historical collection site known to harbor large numbers of both *P. caddoensis* and *P. serratus*. The locality is in the Ouachita National Forest along Forest Rd 73 (ca. 0.8 km S St Hwy 8), Montgomery County, southwestern Arkansas, USA (Trauth and Wilhide 1999. J. Arkansas Acad. Sci. 53:125–137). The sky was clear, the air temperature was ca. 17.0°C, and the ground surface litter was dry. This region of the National Forest had received moderate rainfall two days prior to our arrival. The oak/hickory forest habitat is an east-facing, moderately-sloping embankment of small, loose talus; the bank steepens sharply along an intermittent stream. Initially, we utilized an established collection technique involving the removal of surface rock in swaths to reveal salamanders hidden within the interstitial spaces of the top 20–30 cm of rock talus in the riparian zone. Although this method was successful, collectors began noticing both species of salamanders on the exposed surfaces of small-to-intermediate sized boulders. Moreover, 11 of 52 (21%) *P. caddoensis* were taken from the trunks of trees up to a height of 50 cm. In more than one instance, individuals of both species were found together on the tops of boulders. In addition to the 52 *P. caddoensis*, 45 *P. serratus*, and 3 *Eurycea m. multiplicata* were found at this streamside habitat.

Jaeger (1978. Copeia 1978:686–691) noted that terrestrial salamanders (e.g., *P. cinereus*) that climb plants at night consume a significantly larger volume of food than do non-climbing conspecifics. An apparent lack of aggressive behavior between *P. caddoensis*, a larger species (in our sample, average SVL 37.33 ± 10.6 mm; range 16–52) as compared to *P. serratus* (28.16 ± 8.75; range 18–45), presumably allows each species to coexist syntopically both above and below the ground surface.

We thank the Department of Biological Sciences, Arkansas State University, for providing financial support for this field study.

SIREN LACERTINA (Greater Siren). **AESTIVATION CHAMBER.** Detailed descriptions of the aestivation chamber and cocoon of aquatic salamanders in the family Sirenidae are known primarily from captive individuals of *Siren intermedia* (Reno et al. 1972. Copeia 1972:625–631) and *S. lacertina* (Etheridge 1990. Herpetologica 46:400–406) that were induced to aestivate in laboratory containers. However, observations of aestivating sirens in the field are limited. Carr (1940. Univ. Florida Publ., Biol. Sci. Ser. 3:1–118) found several *S. lacertina* aestivating beneath the surface of a dried wetland, each in a spherical chamber connected to the surface through a narrow vertical tunnel. Freeman (1958. Herpetologica 14:130) found two *S. lacertina* in a recently dried pond bottom buried in hard, moist mud under a mat of dead water hyacinth (*Eichhornia crassipes*); one individual in a vertical tunnel that extended to the surface and the other 10 cm below the surface in a horizontal chamber slightly longer than the body. Here I report an additional field observation of the aestivation chamber of *S. lacertina* along with associated environmental conditions.

On 2 December 1999 at the Megginnis Arm of Lake Jackson, Leon Co., Tallahassee, Florida, USA, I discovered an adult *S. lacertina* (61 cm TL, 48 cm SVL, 700 g) in its aestivation chamber, which had been uncovered by a bulldozer during a sediment-dredging operation. The chamber was located 30 m from the waterline and ca. 15–20 cm below and parallel to the ground surface in moist organic/silt lake sediments under a dense growth of smart-

FIG. 1. Aestivation chamber of *Siren lacertina*.

FIG. 2. Aestivating *S. lacertina* encased in moisture-conserving cocoon. Note S-shaped body position.

weed (*Polygonum densiflorum*) (Fig. 1). There are no previously published photographs of *Siren* in its aestivation chamber in nature, as the chamber is usually destroyed in the process of digging to find the animals. The siren was alive and inactive within a cocoon that consisted of a thin layer of dry skin that covered the body; the skin under the cocoon was moist and the gills were atrophied. The posterior half of the animal was curled back around so that the tail was in slight contact with the body (Fig. 2). This S-shaped body position and the spherical position observed by Carr (*op. cit.*) may help sirens minimize water loss during extended periods of aestivation.

During 1998 and 1999 northwest Florida experienced drought conditions (1999 rainfall 39.7 cm below normal average; NWS, Tallahassee, Florida) and lake waters had not covered the area above the aestivation chamber for 1–2 yr. Therefore, the individual uncovered in this operation was likely in aestivation for at least one year.

Previous observations of sirens in aestivation chambers are only from completely dried ponds where they apparently became trapped and were forced to aestivate (Carr, *op. cit.*; Freeman, *op. cit.*). In the present observation, the lake level was lower due to drought but a large area of open water (> 1 m deep) with a mud bottom and little aquatic vegetation was still available. This observation suggests sirens may aestivate far above drought-lowered waters in areas that were previously inundated, rather than moving with the slowly receding waters to remain active. Numerous other *S. lacertina* and *Amphiuma means* were uncovered in the same area.

ANURA

ELEUTHERODACTYLUS GUTTILATUS (Spotted Chirping Frog), ***BUFO PUNCTATUS*** (Red-spotted Toad), ***HYLA ARENICOLOR*** (Canyon Tree Frog), and ***RANA BERLANDIERI*** (Rio Grande Leopard Frog). **MITE INFESTATION**. Little is known about the infestation of adult amphibians by chiggers, the parasitic larval stage of mites. Here we report the occurrence of two mite species, *Hannemania hylae* and *Hannemania* sp. (Acari, Leeuwenhoekiidae), on four amphibian hosts. Chiggers were found on spotted chirping frogs, red-spotted toads, canyon tree frogs, and Rio Grande leopard frogs in Big Bend National Park (BBNP), Brewster Co., Texas, USA, from June–October 1998 and from May–September 1999. Chiggers collected for this study are housed at the Florida State Collection of Arthropods.

Rio Grande leopard frogs found along the banks of the Rio Grande (elevation 550 m) were infested with an undescribed species of *Hannemania*. The new species is similar to *H. anurae*, which is known only from anurans in western Mexico (Jalisco, Nayarit, and Sinaloa) (Welbourn and Loomis. 1970. Bull. South. California Acad. Sci. 69:65–73).

Canyon tree frogs infested with *H. hylae* were found in slickrock canyons of the Chisos Mountains (elevation 2000 m). This is the first reported *H. hylae* from BBNP. Spotted chirping frogs from the Chisos Mountains were also infested with *H. hylae*, (see also Gaige 1931. Copeia 1931:63; Jameson 1952. Ph.D. Diss. Univ. Texas, Austin; Lynch 1970. Univ. Kansas Publ. Mus. Nat. Hist. 20:1–45.).

We did not find chiggers on *Rana catesbeiana* (bullfrog, N = 13), *Bufo debilis* (green toad, N = 8), *Bufo speciosus* (Texas toad, N = 48), *Scaphiopus couchii* (Couch's spadefoot, N = 43), or *Gastrophryne olivacea* (western narrow-mouthed toad, N = 7). We did find one of 31 (3%) red-spotted toads infested with mites (51 on throat, abdomen, limbs, and digits), but did not collect mites for identification. This toad was found on 7 June 1999 at 0158 h on the road near Panther Junction. It is likely that the chigger on the red-spotted toad was *H. bufonis*. The range of *H. bufonis* corresponds to that of the red-spotted toad in the southwestern USA.

Infestation rates on anurans at BBNP were similar to previous reports. Seventy-one of 81 (88%) Rio Grande leopard frogs captured along the Rio Grande had chiggers. The average number of chiggers on Rio Grande leopard frogs was 45 (range 3–140). Infestation rates were highest on the hind limbs, particularly the thighs. Likelihood ratio chi-square analyses revealed significant differences in frequencies of no, light (1–10 chiggers), moderate (11–50), and heavy (> 50) chigger infestation between juveniles and adults ($\chi^2 = 8.9$, df = 3, P = 0.032) and between adult males and females ($\chi^2 = 16.1$, df = 3, P = 0.001). Twenty percent of the

juvenile frogs were not infested with chiggers compared to 10% of the adults. More male frogs were heavily infested with chiggers (35%) compared to females (13%). Rio Grande leopard frogs (n=24) captured at springs or along roads away from the Rio Grande did not have mites.

Twenty of 25 (80%) adult and 10 of 12 (83%) recently metamorphosed canyon tree frogs were infested with *H. hylae*. Canyon tree frog adults had 6–105 mites, whereas recently metamorphosed individuals had 3–17 mites, though the difference was not statistically significant (Mann Whitney U = 2.0, df = 1, P = 0.12). *Hannemania hylae* were also found on two of three spotted chirping frogs (67%). Individual spotted chirping frogs were infested with 12 and 38 *H. hylae*.

Chiggers are parasites of vertebrates and feed by secreting histolytic enzymes into the host tissue and ingesting the predigested tissue (Jones 1950. Parasitology 40:247–260). Unlike most chiggers that feed by inserting only their chelicerae into the host tissue, *Hannemania* embeds and encapsulates itself in the dermis of the host (Hyland 1961. Exp. Parasitol. 11:212–215; Duszynski and Jones 1973. Int. J. Parasitol. 3:531–538). The *Hannemania* observed on anurans in BBNP formed reddish-orange bumps on the throat, abdomen, and cloaca and on ventral surfaces of the limbs, digits and webbing of the digits. Heavier chigger infestations in male as compared to female salamanders (Anthony et al. Am. Midl. Nat. 132:302–307) have been documented previously, but our study appears to be the first to document heavier infestations in older as compared to younger anurans. Certainly, heavily infested individuals might exhibit greater physical health problems compared to less infested ones. Welbourn and Loomis (1975. Bull. South. California Acad. Sci. 74:15–19) recaptured 196 of 256 marked and chigger-infested *P. cadaverina* (California chorus frog) at least once over a 24-month study in Joshua Tree National Monument, California, suggesting that *Hannemania* infestations may not be lethal to anurans.

Two hypotheses could be generated why Rio Grande leopard frogs are heavily infested with chiggers along the river but not inland. Higher densities of Rio Grande leopard frogs along the Rio Grande (e.g., an average of 158 frogs along the banks of a 7-km stretch in BBNP, unpubl. data) could elicit higher transmission and densities of parasites. Alternatively, the post-larval instars of *Hannemania* live in the soil and may survive better in certain habitats (e.g., riverine) than in others.

We thank Raymond Skiles and Vidal Davila for their wonderful support, and Kevin E. Bonine, Gage H. Dayton, Sandra Raimondo, Andre de la Reza, Michele L. Rosenshield, and Stephen J. Williamson for their field expertise.

Submitted by **ROBIN E. JUNG, SHANNON CLAESON, J. ERIC WALLACE,** USGS Patuxent Wildlife Research Center, 12100 Beech Forest Road, Laurel, Maryland 20708-4038, USA, and **W. CALVIN WELBOURN, JR.**, Florida Department of Agriculture and Consumer Services, Division of Plant Industry, P.O. Box 147100, Gainesville, Florida 32614-7100, USA (e-mail: robin_jung@usgs.gov).

MANTELLA LAEVIGATA (Climbing Mantella). **ABORTED PREDATION**. Predation on members of the genus *Mantella* is probably rare, due to the presence of toxic skin alkaloids, which they share with the dart-poison frogs (Dendrobatidae). I report observations of a successful predation on *M. laevigata* by the cordylid lizard *Zonosaurus madagascariensis*, and an aborted predation by the boa *Boa madagascariensis*. Both observations involved frogs from marked populations on the island of Nosy Mangabe, Toamasina province, Northeastern Madagascar.

On 26 Feb 1997, I observed an adult zonosaur with a mantella in its mouth. The lizard tossed the frog into the leaf litter and proceeded to lick its lips, and rub its snout and entire head on litter and roots, for ten minutes. The discarded frog appeared to be dead. The lizard found the frog corpse and picked it up in its mouth again, shaking it back and forth furiously, and then dropped it. This sequence was repeated three more times. The fifth time the lizard was observed picking up the *M. laevigata* corpse, it ate it head first, leaving the frog's legs sticking out of its mouth while it rubbed its snout on the ground. I was unable to catch the zonosaur to monitor its health after this predation.

On 12 March 1997, during a courtship between two *M. laevigata*, a boa came out from under the leaf litter and captured the female in its mouth. The male *M. laevigata* dove under the leaf litter, and all frog calling and activity in the area stopped. The snake held the frog in its mouth, occasionally appearing to masticate. After twenty minutes, the snake suddenly released the frog, thrusting its open mouth forward to propel the frog onto the litter, and disappeared back under the leaves. The frog was bloodied on her dorsum and head, but hopped away. The next day the boa had left the area, and was not seen again before my departure in early May. On 20 March, the female frog was observed in courtship again, within 5 cm of where she was attacked by the boa. She was observed in courtship six more times between 20 March and 13 April, two of which resulted in oviposition. On April 13, she was observed to deposit a trophic egg for a tadpole, presumably hers, in a well where she had been seen in courtship on multiple occasions. The aborted predation by the boa thus appeared to have no lasting effects on her health or reproductive success.

Mantella laevigata appear to be severely distasteful to both zonosaurs and boas, which probably explains the usual cohabitation of the densely populated zonosaurs and *M. laevigata*, even though zonosaurs prey on other sympatric frog species.

The zonosaur predation observation would not have been possible without Jessica Metcalf, whom I thank for several months of invaluable field assistance.

PHILAUTUS BOMBAYENSIS (Bombay Oriental Shrub-frog). **REPRODUCTION.** The Asian genus *Philautus* contains species of the subfamily Rhacophorinae (Ranidae) that are characterized by direct development, i.e., without an aquatic, free-swimming tadpole. Although 84 species are currently recognized in this genus (Bossuyt and Dubois 2000. J. South Asian Nat. Hist., *in press*), the number of species for which this particular mode of reproduction has been observed is limited. For the Western Ghats of South India, it has been described for only two species, "*P. variabilis*" (Patil and Kanamadi 1997. Current Sci. 73[8]:697–701) and *P. tinniens* (Bossuyt and Dubois, *op. cit.*). We here report on a third

species from the Western Ghats showing such direct development.

During the night of 29 July 1996, we observed axillary amplexus of *P. bombayensis* at an oviposition site in Sakleshpur (12°59'N, 75°43'E), Karnataka. Adult males, sitting on leaves of *Lantana camara* shrubs, were calling from heights between 0.5 and 2 m. The frogs were nocturnal, as no individual was observed during a full day search at this locality.

We observed three clutches, two containing 26 and one 27 eggs, attached to the upper side of leaves (Fig. 1) of *L. camara*, where they were kept humid by the moisture of the dense vegetation. The reproduction of *P. bombayensis* can be referred to mode 20 of the table of reproductive modes in anurans (Duellman and Trueb 1986. Biology of Amphibians: McGraw-Hill, Inc., New York. 670 pp.). This is unlike *P. tinniens* from the Western Ghats, which lays its eggs under stones or tree trunks (mode 17).

Freshly laid eggs of *P. bombayensis* are non-pigmented and uniformly cream colored. This coloration is retained until the forelimbs and hindlimbs are visible as distinct buds (stage 5; Patil and Kanamadi, *op. cit.*). In this stage, the embryos have the head and body arched over the yolk, and are very active in the jelly. They remain in the egg at least until stage 9 (Patil and Kanamadi, *op. cit*) in which the hindlimbs, mouth, eyes, and nasal pits are well developed. In this stage, the tail is slightly longer than the body, and curved along the side of the yolk.

PSEUDACRIS STRECKERI ILLINOENSIS (Illinois Chorus Frog). **TERRESTRIAL FEEDING**. *Pseudacris streckeri illinoensis* is known for its habit of burrowing with its front limbs (Brown et al. 1972. Herpetologica 34:212–216), its restriction to sandy habitats (Brown and Rose 1988. Illinois Nat. Hist. Sur. Biol. Notes 132:1–13), and its ability to feed underground (Brown 1978. Herpetologica 28:325–328). Little is known about its feeding habits because of its secretive nature. Tucker (1997. Herpetol. Nat. Hist. 5:83–87) described the food habits of this frog from Madison County, Illinois. Frogs in this study were collected in Clay County, Arkansas, USA, near Nimmons. This appears to be the first observation and description of terrestrial feeding in *P. s. illinoensis*.

Several individuals had been housed in a plastic terrarium with a sand substrate since their date of collection (23 Feb 2000). The following is a summary of observations on one animal. The specimen sat motionless as the crickets wandered about the sand substrate. After about a minute, the frog leaped at and grabbed a cricket about 10 cm away. Both the tongue and the forelimbs were utilized to capture the prey. It ate 3 crickets in succession, one of which was grasped only with the forelimbs then shoved into the mouth, then refused to eat more. The use of the forelimbs while feeding has not been previously reported. It is likely that while burrowing in the sand, these frogs would encounter prey. The emphasis on forelimb use during feeding likely evolved as an adaptation to an underground existence, as the tongue would be of little use in the subterranean environment. They probably touch the prey with their forelimbs or nose as they burrow (possibly initially detecting the movement of the invertebrate). They then could grasp the insect from the soil with their forelimbs and shove the prey into the mouth as they do above ground. This hypothesis of subterranean behavior is supported by the observation reported herein. As it grasped the cricket with both limbs, the fingers curled around the insect in a manner making it quite difficult for the insect to escape. The captive frogs in this study leave many open burrows throughout the sand. Often the frogs can be observed sitting motionless within a few cm of the entrance. Occasionally crickets were observed entering burrows without ever exiting. It is quite possible that the behavior of these animals is to wait at the bottom of the burrow until a cricket enters, then lunge forward, grab it, and swallow it without ever being seen. This is a highly secretive frog, and little is known of its natural history. Despite housing 12 animals from late Feb–June 2000, this is the only incidence of above ground feeding we observed, yet all crickets introduced into the terrarium regularly disappeared.

Submitted by **MALCOLM L. McCALLUM**, Environmental Sciences Ph.D. Program, P.O. Box 847, Arkansas State University, State University, Arkansas 72467, USA, and **STANLEY E. TRAUTH**, Department of Biological Sciences, P.O. Box 599, Arkansas State University, State University, Arkansas 72467, USA.

RANA AURORA AURORA (Northern Red-legged Frog). **MOVEMENT**. *Rana aurora aurora* is known to utilize a variety of habitat types, ranging from fully aquatic breeding sites to riparian and mesic upland forests during its post-breeding active season. (e.g., Gomez and Anthony 1996. Northwest Sci. 70:109–119; Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Press of Idaho, Moscow, Idaho. 332 pp.). In addition, Licht (1969. Can. J. Zool. 47:1295) implied upland habitats may be used during overwintering at low elevations. Partly as a consequence of these patterns, this species is believed to move large distances. Estimates of the spatial scale of movements are limited to two general statements: Dumas (1966. Copeia 1966:62) stated that "Adult *aurora* are...found...as much as 1,000 yds [≅ 914 m] from the nearest water;" and Nussbaum et al. (*op. cit.*) noted finding *R. a. aurora* in "moist forest situations 200 to 300 m from any standing water." In this note, we provide data illustrating that movements at least 2.6 times the distance of those previously reported can occur, and that movements over 1 km may not be uncommon.

Our observations of *R. a. aurora* movement were made as part of an ongoing study within a Research Natural Area ranging between 500–800 m elevation in the South Umpqua basin of southwestern Oregon, USA. The study area includes a complex of relatively undisturbed mixed coniferous forest interdigitated with savanna-like first- and second-order drainages that convey surface water into early summer. Since initiation of the study in 1999, we have recaptured four PIT-tagged frogs that moved distances greater than those indicated by Dumas (*op.cit.*). On 20 Dec 1999, we captured an adult female *R. a. aurora* (SVL 101.0 mm; mass 75.0 g), at a 0.6-ha pond at which this species breeds. This frog was recaptured on 13 May 2000 in a small (0.05-ha) seasonal pond located 2.4 km (straight-line distance) west of the breeding pond. An adult male (SVL 64.5 mm; mass 19.2 g) recaptured in the same seasonal pond on the same date as the aforementioned female was

originally captured in a mesic draw at a point 1.2 km west of the seasonal pond on 22 April 2000. A second adult male (SVL 60.0 mm; mass 20.5 g), first captured in the same mesic draw as the previous male on 14 Nov 1999, was recaptured in the aforementioned breeding pond 1.3 km to the east on 20 Dec 1999. A third adult male (SVL 70.0 mm; mass 27.6 g), first captured in the breeding pond on 18 Jan 2000, was recaptured in the same mesic draw at a point 1.1 km to the west on 22 April 2000.

Our observations confirm that *R. a. aurora* adults can undertake movements at distances significantly greater than previous estimates. Additionally, since the female was recaptured at a pond that dried within a month after the May survey, the distance of the move we observed may still not represent an active-season maximum. We also emphasize that our observations of *R. a. aurora* movement, which describe distances traveled between capture points regardless of proximity to water, should be distinguished from previous observations referencing only distances to nearest water.

An Oregon Zoo Foundation Grant supported this study; frogs were handled under a Scientific Taking permit from the Oregon Department of Fish and Wildlife.

ROMBOUGH**, P.O. Box 365, Aurora, Oregon 97002, USA (e-mail: rombough@mailbox.orst.edu).

RANA HECKSCHERI (River Frog). **ECTOPARASITES**. The genus *Argulus* (Crustacea: Branchiura: Argulidae) comprises free-swimming ectoparasites that primarily parasitize fish with few records on amphibians (Bower-Shore 1940. Parasitology 32[4]:361–371; Goin and Ogren 1956. J. Parasitol. 24[2]:172; Sauer 1977. Mikrokosomos 66[1]:19–20). Goin and Ogren (*op. cit.*) reported the occurrence of *A. americanus* on *Rana heckscheri* tadpoles at Newnan's Lake in Alachua County, Florida.

During November 1999, I collected argulid specimens from *R. heckscheri* tadpoles while collecting data about the effects of water depth, vegetation density, and substrate type on argulid parasite intensity of *R. heckscheri* tadpoles. The sites surveyed are borrow pits located in Osceola National Forest northwest of Ocean Pond, Columbia County, Florida, USA. Of the 202 argulids identified, 182 were *A. americanus*, and the remaining 20 were *A. diversus*, which is the first documented occurrence of this argulid species on *R. heckscheri* tadpoles.

I thank Eric B. Anderson for assistance in the field, William J. Poly (Southern Illinois University) for identifying the argulids, and Max A. Nickerson (UF/FLMNH) for his support and guidance.

SPEA HAMMONDII (Western Spadefoot Toad). **ELEVATION RECORD**. The highest elevation reported for *Spea hammondii* was 1380 m (Zeiner et al.1988. California's Wildlife. Vol. 1, California Dept. Fish and Game). The location was presented as "the southern Sierra foothills," although no supporting details were provided. Therefore, it is difficult to assign a level of certainty to this record. Herein we provide documentation of three high elevation populations of *S. hammondii* in southern California.

On 13 April 2000, AEA collected 3 large (Gosner Stage 45) *S. hammondii* larva (California Academy of Science 212367, 212368) from a small ground level cement basin (ca. 2 m diameter by 30 cm deep) at ca. 1410 m at San Diego State University Sky Oaks Research Station at the east portion of Chihuahua Valley, San Diego Co., California, USA (33°22'30"N, 116°37'15"W). There were >100 larva present in the pool at the time of collection. The vegetation was characterized as a red shank chaparral community (*Adenostoma sparsifolium*).

On 2 July 1999, ELE and REM collected one metamorphic *S. hammondii* toadlet (CAS 212369; 3.2 cm SUL) DOR on Chihuahua Valley Rd., San Diego Co. (33°23'00"N, 116°41'49"W). This observation was made on the west end of the valley at 1280 m. North of this location is a gently sloping grassland with interspersed scrub plants and scattered mature oak trees (*Quercus agrifolia*); vegetation on the south is dominated by a red shank chaparral community. On 16 July 1999, TLC and ELE collected six metamorphic *S. hammondii* (CAS 212362–212366) from a pool located in Tierra del Sol, San Diego Co. (32°37'57"N, 116°20'27"W). This small pool, at 1180 m, measured 3 m diameter and 0.5 m deep. Associated vegetation is a red shank chaparral community.

Thanks to Joe Copp and Jeremy Pitman for informing us of calling spadefoots in Chihuahua Valley, and to Robert Fisher who provided encouragement and support.

XENOHYLA TRUNCATA (NCN). **ANTIPREDATOR BEHAVIOR**. *Xenohyla truncata*, a hylid treefrog from southeastern Brazil, inhabits terrestrial bromeliads in "restinga" environments (see Eiten 1992. Ann. Acad. Bras. Ci. 64, suppl. 1:35–65). The first observation of defensive behavior in *X. truncata* was reported by Silva et al. (1987. Resumos XIV Congr. Bras. Zoologia:123). The authors reported *X. truncata* showed tanathosis when specimens fell to the ground, although did not provide data about the posture adopted by these specimens. An adult *X. truncata* (Museu Nacional/Rio de Janeiro 23472) collected from a terrestrial bromeliad at Barra da Tijuca, city of Rio de Janeiro, State of Rio de Janeiro, Brazil (ca. 22°54'S, 43°12'W), was carried to the laboratory to be photographed. Immediately upon being placed on a table, the specimen assumed a defensive behavior, stretching the hind limbs out, inflating the lungs, and becoming motionless (Fig. 1). A similar posture was observed in *Eleutherodactylus curtipes* (Duellman and

FIG. 1. Defensive stance of an adult *Xenohyla truncata*.

Trueb 1986. Biology of Amphibians. McGraw-Hill Book Company, New York. 670 pp.). Azevedo-Ramos (1995. Rev. Brasil. Biol. 55:45–47) observed a similar behavior in *Hyla geographica* (= *H. semilineata*) from Juréia, State of São Paulo, Brazil, although the outstretching of the hind limbs was not as great and occurred primarily when the frog was held by its head. This observation supports the hypothesis of Azevedo-Ramos (*op. cit.*) that the outstretched limbs, accompanied by the inflation of the lungs may prevent or inhabit the ingestion of the prey. The outstretched hind limbs associated with immobility in *X. truncata* may be a hard-to-ingest-prey posture in a stress situation or a disruptive posture that breaks the outline of the frog in the case of visual oriented predators (Azevedo-Ramos, *op. cit.*; Sazima 1978. Biotropica 10:158).

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle) and ***ERETMOCHELYS IMBRICATA*** (Hawksbill Sea Turtle). **PREDATION**. Sea turtles are subject to pressures from a wide variety of predators, at many different life stages (Dodd 1988. U.S. Fish Wildl. Serv. Biol. Rep. 88[14]:1–110). Predation pressure seems to be inversely related to age and size of sea turtles— hatchlings are eaten by many species of fish, birds, and mammals while adult turtles at sea apparently have few natural predators, other than sharks and killer whales. Nesting sea turtles face land predators, such as jaguars (Autar 1994. Mar. Turt. Newsl. 67:11–12) and crocodiles (Ortiz et al. 1997. Chel. Conserv. Biol. 2:585–587), not to mention people. Additionally, there have been reports of predation by feral dogs on nesting female sea turtles (Caldwell 1959. Bull. Florida State Mus. 4:319–348; Hendrickson 1958. Proc. Zool. Soc. Lond. 130:455–535). Here, we report domestic dogs attacking and killing nesting sea turtles *Caretta caretta* and *Eretmochelys imbricata*.

Early in the morning of 26 October 1998, the Projeto TAMAR-IBAMA base in Praia do Forte, Bahia, Brazil (12°34'56"S, 38°00'02"W), received a phone call that a large turtle on Guarajuba beach was being attacked by two dogs. Two biologists rushed to the scene, only to find a dead adult *C. caretta*, with its carotid artery punctured. The turtle had begun to dig a nest-hole, but had not successfully laid its eggs before being attacked. The turtle was transported back to the Projeto TAMAR base and necropsied. The gravid female contained 141 eggs in her oviducts. Witnesses identified the dogs and their owner as the same ones responsible for killing a nesting hawksbill (*Eretmochelys imbricata*) on 2 February 1998, during the previous nesting season. Similarly, the *E. imbricata* had been attacked close to sunrise and killed prior to oviposition. This turtle was also necropsied, and 128 unlaid eggs were found in the oviducts. In both cases, the unlaid eggs were washed in fresh water and interred in an open air hatchery at the Praia do Forte station; only the *C. caretta* eggs hatched, producing 43 live hatchlings.

The enforcement authorities at IBAMA and the Institute of the Environment and Natural Renewable Resources of the Federal Government of Brazil were notified, and we expect the owner to face the maximum possible fines. The *C. caretta* carapace now hangs in the museum of the visitor center in Praia do Forte, Bahia, and that of the *E. imbricata* is displayed in visitor center in the archipelago of Fernando de Noronha, Brazil.

Projeto TAMAR is affiliated with IBAMA, co-managed by the Fundação Pró-TAMAR, and its official sponsor is Petrobras. Partial funding also came from the Natural Sciences and Engineering Research Council of Canada.

CHELYDRA SERPENTINA (Common Snapping Turtle) and ***EMYDOIDEA BLANDINGII*** (Blanding's Turtle). **PARASITES**. Nematode and hirudinean parasites have been reported for *Chelydra serpentina* and *Emydoidea blandingii* in North America (see Baker 1987. Mem. Univ. Newfoundland Occas. Pap. Biol. 11:1–325; Watermolen 1996. J. Fresh. Ecol. 11:211–217), but few reports exist from Wisconsin, USA (Gulford 1959. Trans. Wisconsin Acad. Sci. Arts Letters 48:121–124; Amin 1981. Trans. Amer. Micros. Soc. 100:42–51; Watermolen 1996, *op. cit.*). Of these studies, Gulford (*op. cit.*) sampled for helminth parasites among several turtle species, including six *C. serpentina* and one *E. blandingii* from northeastern Wisconsin. Amin (*op. cit.*) reported one *Placobdella parasitica* and three *P. ornata* leeches from a single *E. blandingii* from southeastern Wisconsin, and Watermolen (*op. cit.*) reported *Desserobdella picta*, an amphibian leech, from a snapping turtle from Green Bay, Wisconsin. Here, I report a new locality record for nematodes of *C. serpentina* in Wisconsin and report prevalence and mean intensity data for nematode and leech parasites of *C. serpentina* and *E. blandingii* from eastern Wisconsin.

Turtles were collected by hand or dip-net at the Carroll College field station located in Genesee Depot, Waukesha Co., and at a pond in Wauwatosa, Milwaukee Co. Live-caught turtles were in-

spected for leeches, measured, and released. All leeches were placed in individual vials and relaxed by slowly dripping 95% ethanol into the vial, they were then fixed in 10% formalin. Leeches were identified using a stereo microscope and keys provided by Klemm (1991. Michigan Acad. 24:37–103) and Sawyer (1972. Illinois Biol. Monogr. 46:1–154). Prevalence is the percentage of infected turtles in a sample; mean intensity is the mean number of worms per infected turtle. In addition, three road-killed specimens (two *C. serpentina*, one *E. blandingii*) were collected in Waukesha and Racine Counties, Wisconsin, during 1995–1998. These turtles were inspected for helminth parasites, and were collected within 24 h of death. Upon necropsy, the digestive tract and internal organs were examined for endoparasites for both *C. serpentina* specimens examined. Only the digestive tract was examined from the single *E. blandingii* necropsied because all other organs were badly damaged. All nematodes were fixed in 10% formalin, dehydrated in 70% ethanol, cleared in glycerol, and identified as temporary mounts according to the descriptions of Hedrick (1935a. Trans. Amer. Microsc. Soc. 54:307–335, 1935b. J. Parasit. 21:397–409) and Baker (1986. Can. J. Zool. 64:228–237). Voucher specimens were deposited in the Harold W. Manter Laboratory, University of Nebraska State Museum, Lincoln (accession no. *Placobdella parasitica* HWML 15008, *Placobdella ornata* HWML 15009, *Falcaustra wardi* HWML 15010, *Spiroxys contortus* HWML 15011).

Among the live-caught turtles, five (71%) of seven *C. serpentina* examined were infected with *Placobdella*, with a mean intensity of 21.2 ± 44. Most turtles contained 1–2 *P. parasitica* and/or *P. ornata* with the exception of one immature turtle that contained one adult and 99 young *P. parasitica*. A total of four *E. blandingii* were collected on seven different occasions. A single *P. ornata* or *P. parasitica* was recovered on three out of seven different dates with a intensity of one. A single *E. blandingii* male (carapace length 200 mm) contained one *P. ornata* on 10 June 1998 and one *P. parasitica* when recaptured on 14 June 1998. In total, 103 *P. parasitica* and three *P. ornata* were recovered from *C. serpentina*, and one *P. parasitica* and two *P. ornata* were recovered from *E. blandingii*. All leeches were attached to the ventral surface of the carapace and/or the limbs of the turtles.

Among the road-killed turtles, one immature *C. serpentina* (100 mm carapace length (CL), 172.4 g) was negative for helminths while an adult male (280 mm CL, 3991.6 g) contained four male and five female *Falcaustra wardi* in the large intestine. Gulford (*op. cit.*) previously reported *Spironura affine* (=*Falcaustra affinis*, Baker 1986 *op. cit.*) in Wisconsin snapping turtles. *Falcaustra wardi* is a common parasite of *C. serpentina* (see Baker 1986 *op. cit.*). However, Wisconsin is a new locality record for this nematode. The road killed female *E. blandingii* (210 mm CL, not weighed because of damage) contained four *Spiroxys contortus* nematodes in the stomach, which previously have been reported by Gulford (*op. cit.*) from the northeastern part of the state.

I thank Susan Lewis (Carroll College) for allowing me access to the field station and James Coggins (University of Wisconsin—Milwaukee) for laboratory space. I would also like to thank Melissa Ewert and Luke Bolek for help in collecting turtles.

Submitted by **MATTHEW G. BOLEK**, Department of Biological Sciences, University of Wisconsin—Milwaukee, Milwaukee Wisconsin, 53201, USA. Present Address: School of Biological Sciences, University of Nebraska Lincoln, Lincoln, Nebraska 68588, USA; e-mail: mbolek@unlserve.unl.edu.

CLEMMYS MUHLENBERGII (Bog Turtle). **ECTOPARASITES.** Bog turtles (*Clemmys muhlenbergii*) are known to be parasitized by the leech *Placobdella multilineata* in Virginia (Saumure and Carter 1998. Herpetol. Rev. 29:98). Herein, we report the occurrence of an additional leech parasite of *C. muhlenbergii*, as well as additional occurrences of parasitism by *P. multilineata* on *C. muhlenbergii* in North Carolina, USA. All leech specimens were deposited in the collections of the North Carolina State Museum of Natural Sciences (NCSM).

On 8 June 1996, a female bog turtle (#28: 87.86 mm CL, 119 g) was captured in Wilkes Co., North Carolina. Two leeches (NCSM P-4701) were collected from the turtle's neck. On 8 June 1997, another adult female turtle (#40: 88.66 mm CL, 130 g) was captured at the same site. Three leeches (NCSM P-4704) were collected from the posterior limb sockets. A final sample on 31 August 1997 from two females (#7: 89.20 mm CL, 130 g; #47: 89.56 mm CL, 125 g) belonging to the same population revealed an additional four leech specimens (NCSM P-4705). The examination of four additional bog turtles (2 M, 2 F) from two other sites in Wilkes Co., North Carolina, on 31 May and 1 September 1996 revealed an additional eight leeches (NCSM P-4698, P-4702). All of the aforementioned leeches were identified as smooth turtle leeches (*Placobdella parasitica*). Previously known hosts for this leech species are numerous and include 17 species of turtles belonging to five different families (Watermolen 1996. J. Fresh. Ecol. 11:211–217). Sawyer and Shelley (1976. J. Nat. Hist. 10:65–97) reported collecting *P. parasitica* from *Sternotherus odoratus* in Union Co., North Carolina.

An additional 10 bog turtles (4 M, 4 F, 2 J) captured between 31 May 1996 and 19 June 1999 in Wilkes Co., North Carolina were found to harbor 13 *Placobdella multilineata* (NCSM P-4699, P-4700, P-4703, P-4706 to 4708, P-4711). Three of these turtles were parasitized by two leeches and the remaining seven were hosts to one leech each. The only previous report of *P. multilineata* on a turtle in North Carolina was by Sawyer and Shelley (*op. cit.*) for a *Chelydra serpentina* from Bertie Co.

We thank D. J. Klemm of the U.S. Environmental Protection Agency for his assistance in identifying the brood-sized leeches. We also thank D. Angell, C. K. Cheshire, D. G. Cooper, R. A. Davis, M. E. Dorcas, J. T. Finnegan, D. W. Herman, D. A. Jackan, J. P. Kelly, S. Lindsay, J. V. Morgan-Davis, V. K. Rice, D. T. Sawyer, T. B. Sawyer, T. J. Thorp, J. L. Warner, and J. S. Zawadowski for their assistance in the field.

KINOSTERNON SONORIENSE (Sonora Mud Turtle). **ATTEMPTED PREDATION**. On 18 September 1999, 1606 h, at Cottonwood Creek, a permanent, intermittent Sonoran Desert stream, Yavapai Co., Arizona, USA, I observed an attempted predation event by *Orconectes virilis* (Virile Crayfish, estimated standard carapace length 55 mm) on a juvenile *Kinosternon sonoriense* (32.98 mm CL, 27.16 mm PL, 6.72 g, estimated 2 yrs old based on plastron rings). The *O. virilis* had seized the *K. sonoriense* transversely in its chelae while the *K. sonoriense* unsuccessfully attempted to swim away. After making the observation, I moved in to capture the turtle, and the crayfish released it and escaped. The turtle was later marked, measured, and released as part of a long-term population study. Taylor et al. (1996. Fisheries 21:25–38) reported *O. virilis* and various other species of crayfish native to north-central and eastern North America have been introduced into Arizona. No crayfish are native to Arizona. The introduction of crayfish has had a devastating impact on all trophic levels in western aquatic communities. Exotic crayfish have reduced diversity of native aquatic plants, invertebrates, and vertebrates in several Arizona streams (Fernandez and Rosen 1996. Effects of the Introduced Crayfish *Orconectes virilis* on Native Aquatic Herpetofauna in Arizona. Arizona Game and Fish Dept., IIPAM Project No. I94054. 56 pp.). At Sycamore Creek, a permanent, intermittent stream at Sunflower, Maricopa Co., Arizona, the population of *K. sonoriense* was large and consistent recruitment occurred prior to the introduction of crayfish in 1985 or 1986 (Rosen 1987. Female Reproductive Variation among Populations of Sonoran Mud Turtles (*Kinosternon sonoriense*). Master's Thesis, Arizona State Univ., Tempe. 80 pp.). Since the introduction of crayfish, there is no evidence of juvenile recruitment into the population of *K. sonoriense* at that location (Fernandez and Rosen 1996, *op. cit.*). Fernandez and Rosen (1996, *op. cit.*) hypothesized that low recruitment of *K. sonoriense* at Sycamore Creek was a result of predation by crayfish upon hatchlings. In laboratory investigations, *O. virilis* killed *K. sonoriense* hatchlings (Fernandez and Rosen 1996, *op. cit.*).

My observation at Cottonwood Creek supports their hypothesis, and demonstrates that juveniles up to two years old, as well as hatchlings, are vulnerable. Not only is this an example of the vulnerability of *K. sonoriense*, but also the vulnerability of entire native communities when exotic species are introduced. Biological invasions are the second leading cause of biodiversity loss in the United States (Enserink 1999. Science 285:1834–1836). The case of crayfish introduction into Arizona may prove to be a good model of how this biodiversity loss occurs.

Submitted by **ANGELA L. SCHWENDIMAN**, Department of Biology, Grand Canyon University, 3300 West Camelback Road, Phoenix, Arizona, 85017, USA; e-mail: aschwendiman@uswest.net.

PODOCNEMIS UNIFILIS (Terecay). **MAXIMUM SIZE**. The maximum straight-line caparace length (CL) of *Podocnemis unifilis* reported by Pritchard and Trebbau (1984. Turtles of Venezuela. SSAR Contributions to Herpetology, No 2. 403 pp.) is 47.5 cm. I report here two turtles from Hato La Trinidad, Rio Guanare Viejo, Departamento Arismendi, estado Barinas, Venezuela, collected by S. Boher, 26 February 1992, with CL measurements of 500 mm and 496 mm. The specimens are deposited in Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 2663–2664 respectively). Other straight-line measurements include: carapace width 353 and 352 mm; shell height of 180 and 180 mm. To my knowledge, these are the two largest *P.unifilis* ever reported in the literature.

Submitted by **CÉSAR LUIS BARRIO AMORÓS**, Fundación ANDÍGENA, Apartado 210, 5101-A Mérida, Venezuela; e-mail: cesarlba@yahoo.com or cesarlba@yahoo.com.

RHYNCHOCEPHALIA

SPHENODON PUNCTATUS PUNCTATUS (Northern Tuatara). **REPRODUCTION**. Tuatara (*Sphenodon*) are found on about 30 offshore islands of New Zealand and are represented by three genetically distinct groups. Populations of the northern tuatara, *Sphenodon punctatus punctatus*, inhabit islands much farther north (35°27' to 37°50'S) than the other two groups, *S. punctatus* ssp. (an undescribed subspecies; Daugherty et al. 1990. Nature 347:177–179) and *S. guntheri*, which inhabit islands in Cook Strait (40°40' to 41°07'S). Although aspects of nesting ecology have been established for the latter two taxa (Cree and Daugherty 1990. New Sci. 1739:22–26; Cree et al. 1991. Tuatara 31:9–16; Thompson et al. 1996. J. Zool., Lond. 238:239–251), this is the first record of nesting activity and egg incubation period for northern tuataras in the wild.

Signs of digging were observed in a grassy clearing on top of Lady Alice Island (35°54'S 174°44'E) during the afternoon of 7 December 1997 (early summer). The soil was dry, hard clay and bore two sets of horizontal claw marks where a fist-sized depression had been dug into the slope. A similar patch of soil, ca.1.5 m away, had been scraped bare. When the clearing was next visited, at dusk on 9 December (2039 h), the nest had been filled with loose soil and vegetation, and on my return at 2316 h, a previously gravid female tuatara was observed sitting next to the now-filled nest burrow. Identification numbers painted on her flanks were still legible. She had originally been caught in this clearing 28 days previously and had been carrying five eggs (determined by X-ray). Loose flanks and dimpling of the skin around the cloaca indicated that she had laid her eggs very recently. Records indicate that she had lost 37 g in mass. Careful excavation of the nest the next night (10 December) showed that it contained five eggs arranged in a single layer, with a thin layer of loose soil in the 1.5 cm gap between the eggs and the hard ceiling of the nest burrow. The small amount of loose soil used to fill the nest may have been the result of the surrounding clay being very hard to break up, and the nest entrance had been filled mainly with vegetation (exotic grasses and weeds scraped from around the entrance). The nest entrance was 8 cm across, with a distance of 2.5 cm from the entrance to the first egg, and 9 cm from the entrance to the back wall. The nest was restored to its original state. At 2211 h that same night, the female tuatara was observed lying on top of the nest site and appeared to be using her hind legs to backfill the nest. She froze in position when she became aware of my presence, and remained there while I moved past her. On 13 December, 5 to 6 nights after the eggs were laid, she was seen within 2 m of the nest site. As the nest was shallow and in a site prone to trampling by visitors to the island, wooden stakes were put in a 1 x 1 m square on 14 December 1997 to mark the site. The site was visually

checked and appeared undisturbed in July 1998. It was raining heavily at the time and water was flowing across the surface of the nest (R. Pierce, pers. comm.). On 15 October 1998, soil subsidence at the entrance and a small air space leading into the nest suggested that the eggs had hatched. Partial excavation revealed that only two eggs remained viable (turgid shells), whereas the other three eggs were empty, crumpled shells with a few 1–2 mm holes in their surface. Two of the dead eggs were removed before the nest was reburied. These turned out to be empty, apart from beetle elytra in one. When the nest was next checked on 5 December 1998, the two viable eggs had apparently hatched (single slit in shell along the long axis with a clean inside surface). The incubation period was therefore longer than 310 days and less than 362 days.

This first report of nesting in northern tuatara reveals many similarities with nesting on islands in Cook Strait, ca. 660–720 km south. On these southern islands, tuatara nest from late October to mid-December, peaking in November. Gravid female tuatara migrate from their home burrows to dig nests in open areas where soil temperatures are warmer. Nests are 10–50 cm deep, the female lays her eggs in a single night and returns to the nest each night for up to a week to fill it with soil and grass and defend it from other female tuatara. Incubation of the eggs takes 11–16 months (Cree and Daugherty 1990. New Sci. 1739:22–26). Northern tuataras do not appear to nest earlier in the year nor to have a markedly shorter egg incubation period than their southern counterparts despite warmer environmental temperatures.

I thank Ray Pierce and David Towns for checking the nest in July and December 1998, Alison Cree for comments on the manuscript, and Hana Ott for help with field work in spring 1997 and 1998.

LACERTILIA

COPHOSAURUS TEXANUS (Greater Earless Lizard). **DIET and BEHAVIOR.** While conducting a carrion insect succession field experiment near Las Cruces, New Mexico, USA, individuals of *Cophosaurus texanus* were observed on three separate occasions consuming *Dermestes* sp. adults and larvae associated with domestic swine (*Sus scrofa*) carcasses, and utilizing the carcasses as basking sites. On 14 July 1998 at 0900 h, a *C. texanus* was observed running up to a carcass and eating *D. maculatus* larvae from beneath it. On both 20 August and 27 August 1998, lizards of the same species were observed basking on the swine carcasses and feeding beneath them. In one instance, a *C. texanus* that was basking on the head of the carcass jumped off and began feeding on *Dermestes* revealed as a human manipulator lifted the other end of the carcass. Although it is well known that *C. texanus* is an insectivore, the consumption of *D. maculatus* has not previously been observed. In addition, this event illustrates the opportunistic use of carrion by these lizards.

We thank Carl S. Lieb for his helpful comments on this manuscript.

EGERNIA CUNNINGHAMI (Cunningham's Skink). **ESCAPE BEHAVIOR.** The escape behavior of prey often reflects a tradeoff between predation risk and the cost of executing escape behaviors (Ydenberg and Dill 1986. Adv. Stud. Behav. 16:229–249). Such tradeoffs have been demonstrated for some lizards, with distance from refuges influencing how close an individual allows a potential predator to approach (approach distance) before fleeing (Bulova 1994. Copeia 1994:980–992; Martin and López 1995. Can. J. Zool. 73:129–132; Cooper 1997. Can. J. Zool. 75:943–947). Here, I report that both predator distance and the presence of conspecifics influence the approach distance of the lizard *Egernia cunninghami* (Scincidae).

On 9 December 1998, I studied the escape behavior of *E. cunninghami* on West Island, a small (11 ha) granite outcrop, ca. 5 km from Victor Harbor, South Australia. Using myself as the potential predator, I measured the approach distance for skinks that varied in their initial distance from refuges. Lizards were sighted initially by scanning the shore with binoculars. Upon sighting a lizard, I noted its position and walked towards it at a slow steady pace. When the lizard fled into a crevice, I measured the distances between 1) myself and the lizard's initial position, and 2) the lizard's initial position and the refuge crevice. In some instances, I approached a pair of lizards (lizards within one body length of each other). For pairs, measurements were taken for the first lizard fleeing into the crevice.

Approach distance was significantly influenced by crevice proximity and conspecific presence (General Linear Model: $F = 50.33$, $N = 23$, $r^2 = 0.81$, $P < 0.001$). Approach distance increased with increased initial distance from a refuge ($P = 0.048$). In addition, lizards in pairs had longer approach distances than single lizards (mean ± SD: pairs = 11.9 ± 3.7 m, single lizards = 2.4 ± 1.3 m; $P < 0.001$).

These observations support the generalization that lizards modify escape behavior in response to changes in predation risk and highlight the need for more detailed study of how social factors influence lizard escape behavior. Studies indicate the potential importance of social cues in the expression of escape behavior in *Iguana iguana* (Greene et al. 1978. J. Herpetol. 12:169–176), *Agama stellio* (Zinner 1967. Israel J. Zool. 16:49–58), *Tiliqua rugosa* (Bull and Pamula 1998. Behav. Ecol. 9:452–455), and *Eumeces laticeps* (Cooper, *op. cit.*). While most lizards spend little time in the presence of conspecifics, increased attention may reveal that social factors generally play a role in the expression of escape behavior.

I thank Andrew Meville for transport to West Island, and Michael Bull for suggesting *E. cunninghami* as a study animal. This research was funded by the National Geographic Society.

HOMONOTA FASCIATA (Ututo; South American Gecko). **OVIPOSITION.** On 6 October 1999, a female *Homonota fasciata* was captured with a Sherman small mammal trap at

Establecimiento Río Blanco, 28 km S, 9.3 km W Andalgalá (Andalgalá 27°36'S, 66°19'W), Salar de Pipanaco, Catamarca province, Argentina. The area is located in the "Monte" province, characterized by shrubby xerophytic steppes and marginal forests with low precipitation (between 80 and 200 mm per year).

The specimen (65 mm SVL, 60 mm regenerated tail length) was kept in a terrarium. On 12 October the female laid one egg, which was eaten by her in the same day. Other eggs were laid (one at a time) on 23 November (broken), 17 December, 27 December, 1999 (broken), and on 12 January and 30 January, 2000. At least one of these was viable, the embryo of the egg laid on 17 December 1999 having developed to approximately stage 42 (55–65 days after egg laying; Lemus et al. 1981. J. Morphol. 169:337–349). The embryo was deposited in the Fundación Miguel Lillo herpetological collection (FML 09253). The last two eggs (11.4 x 9.1 mm and 14.25 x 10.7 mm, respectively) have not yet hatched.

Available data for this species indicates a clutch size of only one (Aún and Martori 1994. Cuad. Herp. 8:90–96), with a maximum of two eggs per year (Cruz 1994. Cuad. Herp. 8:119–125). Our observations indicate that this species can have up to six one-egg clutches per year.

Naturales, Miguel Lillo 251, 4000 Tucumán, Argentina (e-mail: virginia@unt.edu.ar).

LIOLAEMUS LEMNISCATUS (Wreath Tree Iguana), ***LIOLAEMUS TENUIS*** (Thin Tree Iguana). **ENDOPARASITES.** *Liolaemus lemniscatus* and *Liolaemus tenuis* (Tropiduridae) are widely distributed lizards in the south-central parts of Chile (Donoso-Barros 1966. Reptiles de Chile, Ediciones de la Universidad de Chile, Santiago de Chile. 458 pp.). To our knowledge there are no published reports of endoparasites for *L. lemniscatus* and *L. tenuis*. The purpose of this note is to report the oxyurid nematode, *Spauligodon maytacapaci* in both lizard species.

Thirty-six *L. lemniscatus* (mean SVL = 46.0 mm ± 0.31 SD, range = 40–53 mm) and 27 *L. tenuis* (mean SVL = 52.4 mm ± 0.46 SD, range = 45–60 mm) were collected December 1999 and January 2000 at Lenga, Talcahuano, VIII Región, (36°45'S, 73°10'W), Chile. Lizards were fixed in 10% formalin and preserved in 70% ethanol. The abdominal cavity was opened and the esophagus, stomach, and small and large intestines were removed, slit longitudinally, and examined under a dissecting microscope. Each helminth was cleared on a glass slide in undiluted glycerol and upon examination with a compound microscope. All were found to represent life stages of the nematode species *Spauligodon maytacapaci*. Lizard voucher specimens were deposited in the Natural History Museum of Los Angeles County, Los Angeles: *L. lemniscatus* LACM 146291–146293; *L. tenuis* LACM 146286–146290. Nematodes were deposited in the United States National Parasite Collection, Beltsville, Maryland: *L. lemniscatus* USNPC 90042; *L. tenuis* USNPC 90043.

Prevalence (percent of infected lizards in sample), total number of helminths (N), mean intensity ± SD (mean number of nematodes per infected lizard) and range for *S. maytacapaci* were: *L. lemniscatus* prevalence = 17%, N = 17, mean intensity = 2.8 ± 2.4 SD, range = 1–7; *L. tenuis* = 70%, N = 81, mean intensity = 4.3 ± 4.1 SD, range = 1–14.

Spauligodon maytacapaci was described from *Leiocephalus* sp. collected in Cajamarca Province, Peru by Vicente and Ibañez (1968. Atas Soc. Biol. Rio de Janeiro 11:185–187) as *Parathelandros maytacapaci.* It was assigned to its current taxonomic position by Barus and Coy Otero (1974. Vest. Cesk. Spol. Zool. 38:1–12). This report of *S. maytacapaci* in *L. lemniscatus* and *L. tenuis* represents new host records. Chile is a new locality record.

BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **DIET.** On 17 July 1999, we observed the foraging behavior of a male *Phrynosoma cornutum* (90 mm SVL) ca.6 km E Portal in Chochise County, Arizona, USA. At 1710 h, he approached a termite (Isoptera: *Gnathamitermes perplexus*) mating exodus and began feeding on alates (winged reproductives) that were emerging from a single ground opening. During a 25-minute span, he consumed 94 termites. When we left the area at 1735 h, he was still feeding, although his rate of feeding had slowed markedly. During these observations, harvester ants (*Pogonomyrmex* sp.) were observed coming to the ground opening and carrying termites away. The *P. cornutum* made no attempts to capture these ants, which our behavioral observations and fecal analysis indicate compose more than 90% (numerically) of *P. cornutum*'s diet in the study area. While termites have been observed to represent a small portion of the diet for *P. platyrhinos* (Pianka 1986. Ecology and Natural History of Desert Lizards. Princeton University Press, Princeton, New Jersey. 208 pp.), we know of no records of *P. cornutum* feeding on termites, and no record of any *Phrynosoma* species feeding on termites at colony openings.

We thank the Durfee Foundation and Earthwatch Institute for support of fieldwork.

Submitted by **KRISTIN BOTT**, 1755 Gekeler Lane, Boise, Idaho 83706, USA, **TRACEY BROWN**, CRES, Zoological Society of San Diego, P.O. Box 120551, San Diego, California 92112, USA, and **DOUGLAS EIFLER**, Department of Biology, University of Wisconsin, Stevens Point, Wisconsin 54481, USA.

PHRYNOSOMA (Horned Lizards). **PROTECTION.** While examining the horned lizards *Phrynosoma cornutum* and *P. modestum* collected in Chihuahua, Mexico by the first author during the summer of 1999, we encountered a cloacal structure not described previously. This structure is unique to *Phrynosoma* and presumably serves an important function in minimizing attacks by ants and resisting water loss.

The structure is here designated a squamous anal valve. It consists of a specialized groove dorsal to the anterior lip of the

FIG. 1. Ventral view (anterior to the top) of the squamous anal valve in *Phrynosoma modestum*, UBIPRO UNAM field no. JLE 3666, an adult female 55 mm SVL from Polvorillas (= Piedras Encimadas), mpio. Ojinaga, Chihuahua, Mexico (28°47'36.2"N, 104°13'30.8"W), 1440 m, 7 July 1999. The valve is shown spread somewhat to reveal the grooved anterior border with its pavimentous scales blending into the soft tissue of the cloaca, and the cord-like posterior border fortified by narrow, tightly juxtaposed scales. The black patches at each end of the groove and the central black spot posterior to the anus are present in all specimens examined of this species, but not in other species. Their role is not evident.

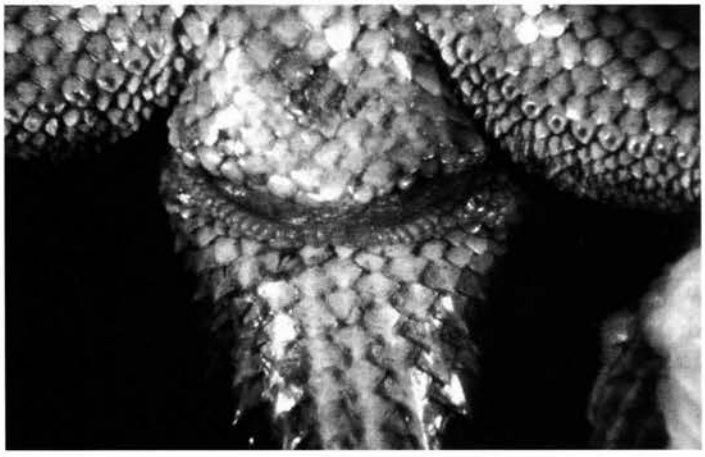

FIG. 2. Ventral view of the anal region (anterior to the top) of *Sceloparus grammicus*, UBIPRO UNAM field no. JLE 3944, an adult female 49 mm SVL, from 8.1 km S Creel, Chihuahua, Mexcio (27°42'6.9"N, 107°35'6.1"W), 21 July 1999. There are no scales posterior (or dorsal) to the anterior lip of the anus, only soft cloacal tissue. The scales on the posterior lip are mostly small; a few are somewhat elongate, but all blend shortly into the soft tissue of the cloaca without forming a distinct cord-like ridge.

anus, receiving a specialized ridge along the posterior lip of the anus. Closed, the valve is as impervious to attack by ants or other invertebrates as are most other surfaces of the body.

The groove distal to the anterior lip of the anus is lined with scales, above and below, although their extent on the dorsal wall of the groove is less than on the ventral wall, which is completely covered. On the dorsal wall the scales diminish in size over a short distance as they blend with the soft flesh of the cloaca. The scales in the groove are pavimentous, flat and juxtaposed, not imbricate.

The scales lining the ridge along the posterior lip of the anus are, in most species of the genus, very narrow and elongate, 2–3 times as long as broad, and they form a solid, dorsoventrally curved cord fitting snugly into the groove of the anterior lip of the anus. No scales lie internal to the ridge scales, which are bordered internally by the soft flesh of the cloaca.

We have examined examples of all species of the genus except *P. douglasi*, finding no fundamental differences among them in the structure of the valve. In some species, the ridge scales on the posterior lip of the anus are less narrow and elongate.

Some members within the genus *Sceloporus* examined exhibit no similar modification of the anal lips, which are less pronounced than in *Phrynosoma*. However, *S. slevini* and both *Urosaurus* and *Uta* have a rudimentary valvular structure, even with the same sort of narrow, elongate scales fortifying the posterior lip of the anus.

We are grateful to Richard R. Montanucci for his advice that the structure here reported merits further investigation, and to William E. Friedman for taking the photographs.

Submitted by **JULIO A. LEMOS-ESPINAL**, Laboratorio de Ecología, Unidad de Biología, Tecnología y Prototipos, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México, Apartado Postal 314, Avenida de los Barrios s/n, Los Reyes Iztacala, Tlalnepantla, Estado de México, México 54090, **HOBART M. SMITH** and **DAVID CHISZAR,** University of Colorado Museum, Boulder, Colorado 80309-0334, USA.

SCELOPORUS BELLI (Bell's Spiny Lizard). **PREDATION.** On 28 August 1999, as one of us (JAL) was collecting herps in a large grassland between Rancho La Paloma and Rancho El John, municipio of Coyame, Chihuahua, Mexico (29°47'55.6"N, 105°21'43.7"W), a small skull was spotted impaled on a spine of a large (ca. 2 m tall) *Yucca elata*. The skull (now JEL 4223, in the herpetological collection of Unidad de Biologia, Tecnologia y Prototipos [UBIPRO]) was of an adult *Sceloparus belli* and measured 10.1 mm in width and 10.0 mm in length. A 37 mm grasshopper was also observed impaled on a nearby spine, and a pair of loggerhead shrikes (*Lanius ludovicianus*) was seen flying in the area. This is the first record of predation on this little-known species.

FIG. 1. Skull of *Sceloporus belli* impaled on a yucca spine.

As can be seen in Fig. 1, the yucca spine penetrated the entire skull, through its roof. It would have taken considerable force to impale the lizard, embedding it so firmly that subsequent consumption of the body never released the skull.

SMITH**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA.

SCINCELLA LATERALIS (Ground Skink)**. FIELD BODY TEMPERATURES and ECOLOGICAL NOTES.** The ground skink, *Scincella lateralis*, is a small, diurnal insectivore that inhabits forested areas and is commonly encountered foraging in the leaf litter. A few detailed studies of this lizard's ecology (Akin 1998. Can. J. Zool. 76:87–93; Duval et al. 1980. J. Herpetol. 14:121–127; Nicoletto 1985. J. Herpetol. 19:487–491) exist but field temperature data are limited (Brooks 1967. Ecol. Mongr. 37:71–87; Fitch 1956. Univ. Kansas Mus. Nat. Hist. 8:417–476). Therefore, we conducted a short survey of field body temperatures and general ecology observations of an urban population of *S. lateralis*.

Field work was conducted on the grounds of the Dallas Zoo (Dallas County, Texas, USA). The study site consisted of a wooded plot adjacent to the zoo's bird and reptile building, measuring approximately 56.7 m x 30.3 m, with the building acting as eastern border for 30 m. Frequently traveled concrete roadways act as the western and northern borders. The study area is characterized by heavy leaf litter, high density of low level vegetation, and debris (large rotting tree limbs). Leaf litter depth ranged from 1.3 cm to 17.8 cm, with the deepest areas adjacent to the building's exterior wall.

From 20 June to 20 July 1998, morphometric data, temperature data, and general ecological observations were recorded for sixty lizards. After data were collected, specimens were released within 2.0 m of the original capture site. The study site was visited 19 times, no more than twice per day, for a mean period of 41.0 minutes per visit. Data were gathered only once for each lizard, with duplicate data excluded from analysis based on morphometric records. Morphometric data recorded included SVL, tail length, head width, mass, sex, and age class. Measurements were taken with calipers to 0.1 mm. Head width was recorded as the distance between each eye. Mass was measured with a 50.0 g Pesola scale. Sex was determined by the observed presence or absence of hemipenes. Specimens with an SVL of 35.0 mm or greater were classified as adults (Brooks 1967. Ecol. Mongr. 37:71–87). Two specimens (1 male and 1 female) were missing their front left feet. See Table 1 for morphometrics.

Individual body (cloacal) temperatures (T_b) were taken within 10 sec of capture. Air temperature (T_a) was recorded approximately 1.5 cm above the substrate. Both T_b and T_a were recorded with a type k thermocouple and digital thermometer (600-0000, Barnant Company, Barrington, Illinois, USA). Substrate temperatures (T_s) were measured with an infrared thermometer (RAYST2PU, Raynger ST, Santa Cruz, California, USA). Weather conditions and degree of sun exposure (shade, indirect, direct, and mosaic) were documented.

Lizard behavior, upon first sighting, was recorded as still, crawling, running, or basking. Basking was indicated when an individual remained motionless for at least 120 sec in direct sunlight. Microhabitat information such as the type of substrate and relative moisture levels was collected. Moisture level was judged by touch, as dry or moist, while the presence of standing water was recorded as wet.

Male mean $T_b = 27.4 \pm 2.8°C$ (N = 25), female mean $T_b = 27.3 \pm 2.6°C$ (N = 30). Mean body temperature for all skinks examined was $27.4 \pm 2.6°C$ (N = 60). Skinks were active at T_a's ranging from 17.8 to 43.3°C ($25.8 \pm 4.0°C$, N = 60) and T_s's from 21.1 to 49.4°C ($29.6 \pm 6.1°C$). Body temperatures never exceeded 31.1°C.

Substrate conditions varied within the skinks' microhabitat. Forty-three lizards were collected in leaf litter: 14 in dry leaves, and 29 in moist leaf litter. Three skinks were recorded on bare soil: two in dry conditions, one on moist soil. Five lizards were also collected on dry rock substrate. An additional eight skinks were found in other forms of refugia (e.g., under plywood, broken pottery): three in dry conditions, four in moist areas, and one on wet substrate.

The majority (62%, 37) of lizards collected were found running, presumably because of our presence. Twenty percent (12) were found slowly crawling, possibly foraging. Eighteen percent (11) were found motionless under leaf litter or some form of refugia. Only one individual was observed basking. Eighty-two percent (49) of individuals collected were found in shaded areas. Seven percent (4) were found in mosaic areas, 7% (4) in indirect sun, and 4% (3) in direct sunlight.

TABLE 1. *Scincella lateralis* mean morphometrics (SD/N).

	Head Width (mm)	SVL (mm)	Tail Length (mm)	Mass (g)
Male	4.4 (0.2/22)	41.0 (2.2/25)	49.3 (16.8/25)	1.3 (0.3/25)
Female	4.5 (0.1/23)	46.6 (3.6/30)	50.2 (17.2/30)	2.0 (0.5/30)

Submitted by **RUSTON W. HARTDEGEN** and **DAVID T. ROBERTS**, Department of Herpetology, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA, and **KATHERINE L. DEADERICK**, Children's Hospital at Medical City Dallas, 7777 Forest Lane, Dallas, Texas 75230, USA.

AMPHISBAENIA

AMPHISBAENA MERTENSI (NCN). **DEFENSIVE BEHAVIOR.** Caudal autotomy—the ability to lose the tail in defensive encounters—is exhibited by some lepidosaurs, salamanders, and a few rodents (Arnold 1988. *In* C. Gans and R. B. Huey [eds.], Biology of the Reptilia, vol. 16, Defense and Life History, pp. 235–273. Alan R. Liss, New York). This behavior is thought to be an important strategy, attracting a predator's attention

to the broken piece of the tail, allowing the prey to escape. Here we report on a provoked predatory encounter between an amphisbaenian, *Amphisbaena mertensi*, and the South American coral snake, *Micrurus lemniscatus*, a natural predator of amphisbaenians (Amaral 1927. Coletânea dos Trabalhos do Instituto Butantan, vol. 2, Oficina do Diário Oficial, São Paulo, 406 pp.). These two species are broadly sympatric over their geographic distribution.

The observations were made with an adult male *A. mertensi* (SVL 284 mm; tail length 47 mm) collected at an animal rescue during the construction of the hydroelectric power plant near Miranda, Patrocínio municipality, Minas Gerais state, Brazil, and an adult female *M. lemniscatus* (SVL 547 mm) collected at Rio Claro municipality region, São Paulo state, Brazil. Both specimens were deposited in the Museum of the Zoology Departament, Universidade Estadual Paulista, Rio Claro, SP (*A. mertensi* under # 974 and *M. lemniscatus* under # 975).

On the evening of 24 May 1999, the animals were placed in a plastic box (73 x 39.3 x 55 cm) with 3.5 cm of soil as substrate and illuminated by a dim infrared light. Thereafter, the animals were left undisturbed and their behavior was recorded by a closed-circuit television system. After 1.5 h, the coral snake directed its head toward the amphisbaenian, moved rapidly toward it, and bit the terminal section of its tail. The tail autotomized at a natural break site immediately following the bite (Vanzolini 1948. Rev. Brasil. Biol. 8:377–400). The movements of the broken piece of the tail attracted the coral snake which spent 3 min inspecting it. After the attack and tail autotomy, the amphisbaenian moved continuously, an activity that, under natural conditions, would probably allow the animal to escape and survive this predation event. Under the experimental conditions, however, the coral snake was able to re-attack 3 h later. At this time, the coral snake again bit the terminal section of the amphisbaenian tail and the amphisbaenian thrashed vigorously, forcing the coral snake to release it. From 19–40 min after this second attack, the *A. mertensi* died, probably due to envenomation from the second attack.

In a sample of 30 *A. mertensi* from the same animal rescue at Miranda, 33% of the individuals had autotomized tails. Assuming that tail loss scars are evidence of survivorship from a predatory encounter, and based on our experimental observations, we conclude that caudal autotomy could serve as an effective defense strategy for *A. mertensi*, resulting in survival from predation in a considerable proportion of individuals.

SERPENTES

AGKISTRODON CONTORTRIX CONTORTRIX (Southern Copperhead). **CHEMOTAXIS, ARBOREALITY and DIET.** Flightless larval cicadas emerge from the ground and often climb into vegetation to complete final ecdysis and emerge from the pupal skin. During the ca. two-hour period of emergence, and as adults, cicadas are susceptible to predation by a variety of organisms (Williams and Simon 1995. Annu. Rev. Entomol. 40:269–295). Copperheads (*Agkistrodon contortrix*) are known to consume periodical cicadas during years of peak emergence (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio; Williams and Simon 1995, *op. cit.*; Reid and Nichols 1970. Bull. Maryland Herpetol. Soc. 6:57). Here, we report an observation of a copperhead that climbed into a cedar tree, used chemotaxis to locate an emerging cicada, and consumed it.

On 21 July 1997 at ca. 2130 h, we encountered an adult male *A. contortrix* (68.2 cm SVL, 274.6 g) ca. 1.3 m high, and climbing, in a cedar tree at the Ozark Natural Science Center, Madison Co., Arkansas, USA. The snake's movements were characteristic of chemotaxis described for viperids trailing in search of stricken prey (Chiszar et. al. 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 369–382. Selva, Tyler, Texas). On a branch ca. 2.2 m off the ground (still about 2 m from the climbing snake), and suspended from the down side, we noticed a single dogday cicada (*Tibicen canicularis*) emerging from its pupal skin. The snake climbed by coiling around the trunk, and using small irregularities on the bark surface and branch remnants (Fig. 1). The cedar tree had multiple trunks arising by splits at ca. 0.5 m. The copperhead climbed a different trunk than the one from which the emerging cicada was suspended. The snake's intensive tongue flicking and head waving suggested that he was trailing the cicada along the same path that the insect took from the ground. The snake climbed up into the branches to a point higher than the cicada and crossed over to the cicada's trunk along a continuous tract of branches. The snake was continuously supported by the trunk or branches, even though bridging the body across gaps would have yielded a more direct path to the cicada. The snake's path would also have been accessible to the crawling cicada nymph. The snake proceeded to a point on the branch directly above the suspended cicada and searched the space below the branch with its tongue until its nose was in contact with the emerging insect. The snake nudged the cicada, which responded with a small movement. Immediately, the snake seized the insect with a quick grasp and swallowed it whole while still suspended from the branch. Use of

FIG. 1. *Agkistrodon contortrix* climbing a straight-trunk cedar tree, tracking a cicada nymph to its point of eclosion. Note use of bark irregularities and branch remnants for climbing.

arboreal habitats while foraging for cicadas has been reported once previously for copperheads (Werler 1978, as cited by Gloyd and Conant 1990, *op. cit.*). Our observation expands this previous report by suggesting that copperheads may use chemotaxis to track and locate recently eclosed cicadas.

Seven nights later, on 28 July 1997, this same snake was observed at 2215 h suspended 1.5 m off the ground in the branches of a cedar tree swallowing another *T. canicularis*. Also, at 2040 h on 28 July 1997, a second *A. contortrix* was observed to climb a small sapling (ca. 1 m in height), knock a cicada off of it, crawl back down, and seize and ingest the cicada on the ground.

Opportunistic ingestion of cicadas by copperheads during years of periodical emergence has been documented (Gloyd and Conant 1990, *op. cit.*; Reid and Nichols 1970, *op. cit.*). Unlike previous reports of copperhead predation on cicadas, our observation did not occur during a peak emergence of a periodical species, but rather seemed a routine predation of annually emerging dogday cicadas. Examination of fecal samples collected from copperheads at our site during July and August 1996 and 1997, revealed that six of seven samples contained remains of cicadas.

Energy density data for *Tibicen* are absent from the primary literature, however, Brown and Chippendale (1973. J. Insect Physiol. 19:607–614) reported that 17-year periodical cicadas (*Magicicada cassini*) in Missouri carry large reserves of lipid and protein upon emergence. The average female *M. cassini* weighed 565 mg wet mass, including 58 mg of lipid and 110 mg of soluble protein. In contrast, the average male *M. cassini* weighed approximately 278 mg, of which 19 mg were lipids and 51 mg were soluble protein. Assuming an energy yield of 38.9 kJ/g for lipids and 17.5 kJ/g for protein (Eckert et al. 1988. Animal Physiology: Mechanisms and Adaptations. 3rd ed. W. H. Freeman & Co., New York, New York. 562 pp.), then the minimum energy content of female and male *Magicicada* would be approximately 4.18 kJ and 1.63 kJ respectively. Temporally abundant, high energy cicadas (especially females), may be an important contribution to the annual energy budgets of copperheads. Other small pit vipers (*Crotalus lepidus*, *C. cerastes*) have annual energy budgets of 1000 to 1300 kJ per year (Beaupre 1996. Copeia 1996:319–329; Secor and Nagy 1994. Ecology 75:1600–1614). Copperheads that gorge themselves on abundant cicadas during summer may acquire significant portions of a similar annual energy requirement.

APARALLACTUS NIGER (NCN). **VARIATION**. *Aparallactus niger* is a fossorial colubrid snake. Previous authors record that the dorsum of this species is uniformly black or blackish-brown (Angel 1933. Les Serpents de l'Afrique Occidentale Francaise. LaRose Editeurs, Paris. 246 pp; Villiers 1950. Les Serpents de l'Ouest Africain. Publications de l'IFAN, Dakar. 148 pp; Wallach 1994. J. Herpetol. 28:95-99). In June–August 1987, I collected 11 *A. niger* from Area J of Yekepa, Nimba County, Liberia. Of these, the dorsum was uniformly black in only four specimens, all more than 30 cm total length (38 cm, 42 cm, 44 cm, and 48 cm). In two other dorsally-black specimens, a light-colored spot was present on each dorsal scale, but the spots were so faint that they were almost invisible; these specimens were also over 30 cm total length (57 cm and 61 cm). In the rest of the specimens, all under 30 cm total length, the dorsal scales exhibited bold dots of the same color as the belly (yellow or light gray). In four of these smaller specimens (21 cm, 21.5 cm, 23 cm, and 25.5 cm), these spots were present only on the anterior portion of the snake. In one small specimen (19 cm), the belly and dorsal spots were gray, while a collar of yellow spots occurred on the nape; this specimen's dorsal spots occurred throughout its length, but some of the anterior dorsals lacked the spot. This sample appears to reveal that juvenile *A. niger* are more boldly marked than adults, and that the coloration of *A. niger* is more varied than had been thought.

I thank Mr. Alfred Yeanay for locating the specimens.

BOTHROPS JARARACA (Jararaca Pitviper). **CAUDAL LURING**. Caudal luring involves moving the distal portion of the tail in a manner resembling a vermiform invertebrate, for the purpose of attracting vertebrate prey (Tiebout 1997. J. Herpetol. 31:292–295). Caudal luring has been reported for juveniles of several species of *Bothrops* (*sensu stricto*), including *B. atrox*, *B. jararacussu* and *B. jararaca*. (Sazima 1992. *In*: Campbell and Brodie [eds.], Biology of Pitvipers, pp. 199–206. Selva, Tyler, Texas). On 12 January 2000 at 0900 h, we observed and photographed caudal luring in a juvenile *Bothrops jararaca* at Mata Atlântica (Parque Estadual da Serra do Mar, Núcleo Picinguaba – Ubatuba – SP, Southeastern Brazil). The juvenile male (29 cm SVL) was coiled on the ground at the edge of a streamlet, in the forest. The snake kept its body completely motionless, except for the distal part of the tail. We observed a potential prey item in the streamlet (*Hylodes asper*, Anura, Leptodactylidae). *Bothrops jararaca* has been reported to employ caudal luring twice during early night (Sazima, *op. cit.*). Apparently this is the first record of caudal luring in *B. jararaca* in the morning.

We thank Célio F. B. Haddad for his comments and review of the manuscript.

BOTHROPS LEUCURUS (White-tailed Lancehead). **REPRODUCTION**. On 6 October 1998, a female *Bothrops leucurus* from Porto Seguro (16°26'S, 39°03'W), an eastern Brazilian city, was received by Instituto Butantan, São Paulo, Brazil. The snake was individually housed in a cage, where it was offered water and mice. On 19 February 1999, the female (SVL 1030 mm, tail length 130 mm, 535 g) gave birth to 17 living neonates (9 males: 8 females) and one stillborn individual of undetermined sex. The neonates were weighed and measured immediately. Male mass ranged from 5.5–6.5 g (mean ± SD = 6.3

± 0.38 g); male SVL ranged from 209–220 mm (214.9 ± 0.44 mm). Female mass ranged from 3.0–7.0 g (6.0 ± 1.25 g); female SVL ranged from 179–222 mm (209.9 ± 1.36 mm). There were no significant differences in mass (t = 0.54; $P = 0.30$) or SVL (t = 0.99; $P = 0.17$) of male and female neonates. The combined mass of the living neonates was 19.57% of the mother's pre-partum mass. The size of this litter is within the published range for this species (5–20; Lira-da-Silva et al. 1994. Rev. Bras. Biol. 11:187–193).

CROTALUS LEPIDUS LEPIDUS (Mottled Rock Rattlesnake). **DIET**. There are few literature reports of North American rattlesnakes preying upon horned lizards (*Phrynosoma* spp.) in the wild (e.g., *Crotalus atrox* and *P. cornutum*, Beavers 1976. Southwest. Nat. 20:503–515; *C. cerastes* and *P. m'calli*, Funk 1965. Herpetologica 21:15–17; *C. viridis* and *Phrynosoma* sp., McKinney and Ballinger 1966. Southwest. Nat. 11:410–412). Herein, we report *C. l. lepidus* preying upon *P. hernandesi*. On 12 September 1999 in the Davis Mountains, on Hwy 118 between Hwy 17 and Hwy 166, Jeff Davis Co., Texas, USA, one of us (RWD) collected a DOR adult female *C. l. lepidus* (516 mm SVL, 40 mm tail) that contained a partially digested *P. hernandesi* (100 mm SVL) that had been ingested head first. The rattlesnake and horned lizard have been catalogued in the University of New Mexico Museum of Southwest Biology (MSB 61422 and MSB 61423).

EUNECTES MURINUS (Green Anaconda). **DIET**. There are few documented reports on the diet or foraging behavior of green anacondas (*Eunectes murinus*). Here we describe green anacondas preying on large mammals in the llanos of Venezuela. All observations were made by XV during a study of wedge-capped capuchin monkeys (*Cebus olivaceus*) in a semi-deciduous gallery forest that extends across two contiguous cattle ranches, Fundo Pecuario Masaguaral (8°34'N, 67°35'W) and Flores Moradas, located 50 km south of Calabozo in Guárico state. The area has well-defined dry (January–April) and wet (June–November) seasons. The gallery forest is characterized by a canopy height of 14–22 m and two permanent watercourses, the Caño Caracol and the Guárico River. A narrow, shallow inlet from the caño penetrates ca. 40 m into the surrounding forest. Three adult anacondas were observed at different times near the distal end of the inlet, in an area well shaded by vines and the forest canopy. The width of the inlet varies depending on water level but is typically 1–1.5 m wide and 10–15 cm deep, whereas the caño is 15–30 m wide and 0.5 m deep. The inlet is filled with leaf litter, fallen twigs, and branches, and at times is covered with a thin layer of floating vegetation (*Lemna* spp.) that may help to conceal the snakes. There is no standing water in the forest at the peak of the dry season, and the caño is the closest source of water for many forest animals.

On 4 March 1998 at 0804 h, capuchin monkeys were observed giving ground-predator alarms at an anaconda that was lying next to and partially beneath a dead adult white-collared peccary (*Tayassu tajacu*, average adult body mass 20 kg). The snake (ca. 5 m TL) fully extended its body, then used its mouth to grab the peccary's snout and drag the body 3 m through the water. While still holding onto the snout, the snake coiled itself round the peccary's torso and squeezed, visibly stretching the peccary lengthwise and forcing out fecal matter (Fig. 1). Stretching large prey may facilitate their ingestion by anacondas. At one point, a muffled crackling sound was heard, resembling that of many bones breaking all at once. The anaconda repeated dragging and stretching the peccary. XV left the inlet at 1128 h to resume following the capuchin monkeys. When the monkeys returned at 1252 h, the anaconda still had not begun to swallow the peccary. The following morning at about 1100 h, both the anaconda and peccary were gone.

On 22 March 1999 at 1331 h, capuchin monkeys were heard giving ground alarms at the same caño inlet. An adult female anaconda (4.0–4.2 m TL) was found with its mouth around the head of an adult lesser anteater (*Tamandua tetradactyla*, average adult body mass 4–6 kg). When next seen at 1456 h, the anaconda had finished swallowing the tamandua.

These are the first documented observations of green anacondas preying on peccaries and tamanduas. In both cases, the anacondas were observed in the same location. On a third occasion, 19 May 1999 at 0923 h, another anaconda (4.5 m TL, and distinguished by photographs of its tail color pattern) was seen within 5 m of the above location, partially submerged and obscured by leaf litter.

These observations of different anacondas in the same inlet suggest that the snakes select this location for foraging and ambushing prey. The shallow, narrow character of the inlet may facilitate the close approach of animals that are foraging or coming to the water for a drink, thus providing a short striking distance for anacondas.

EUNECTES NOTAEUS (Yellow Anaconda). **DIET**. Between June and September 1994, the first stage of filling of the Yacyreta Dam Reservoir, located on the Paraná River along the Paraguayan-Argentinian border (ca. 27°30' S, 56°40' W), occurred. During the flooding we had free access to the specimens of *Eunectes notaeus* captured by an official fauna rescue team. Approximately 1500 yellow anacondas were collected from branches of the flooded trees and bamboos and later released in safe places by the rescue team. We randomly selected 100 specimens that were immediately sacrificed, measured, dissected, examined for fresh stomach contents and reproductive condition, fixed, and later deposited in the Herpetology Section of the Museo Nacional de Historia Natural del Paraguay (MNHNP).

Of these 100 specimens, six had fresh prey items in their stomach, one regurgitated an oppossum while being transported in a sac, and one contained bird feathers in its scat (Table 1). The four prey species encountered have not been previously reported as part of the diet of *E. notaeus* (Strüssmann 1997. Biociências, Porto Alegre 5:35–52). The small proportion of individuals containing fresh prey could be explained by the relatively low temperatures prevailing during our field work, which occurred during the local (subtropical) winter season. We note that the conditions during our research were man-induced (dam filling), however, the filling process and the water levels of the reservoir paralleled the periodical large floodings that affect the Paraná River ca. every 10 years. Thus, we do not believe that this man-induced situation has altered qualitatively the usual prey preferences of the yellow anaconda.

We acknowledge Aida Luz Aquino (Paraguay CITES Scientific Authority) for supporting our research, and Marta Motte (MNHNPY Curator of Herpetology) for her cooperation during our field and museum work.

HELICOPS SCALARIS (Guata). **REPRODUCTION**. *Helicops scalaris* is found aggregated in groups in fresh or brackish waters, where it feeds on amphibians and fish. It is restricted to the Lake Maracaibo basin in Venezuela (Lancini 1986. Serpientes de Venezuela, 2nd ed. Caracas, Venezuela, 262 pp.). On 6 August 1999 two female *H. scalaris* were collected in the coastal portion of northern Lake Maracaibo, Zulia State. Both individuals (950 mm and 1005 mm total length [TL], 570 g and 595 g, respectively) were in late pregnancy. Both snakes were taken to the laboratory for monitoring in captivity. Birth occurred four and one weeks after collection, with litter sizes of 21 and 22, respectively. Offspring from the two litters were similar in size (20.53 ± 0.43 mm TL, 5.22 ± 0.27 g; 20.48 ± 0.35 mm TL, 5.37 ± 0.34 g, respectively). One snake was taken to the snake section of the Aquarium J. V. Seijas in Carabobo State; the other snakes remain alive in the biothery of the Facultad de Ciencias Veterinarias of La Universidad del Zulia, in Maracaibo.

We acknowledge Angel Viloria from the Museo de Biología de La Universidad del Zulia (MBLUZ) for confirming the identity of the species.

HETERODON PLATIRHINOS (Eastern Hognose Snake). **PARASITES**. On 26 April 1998, a 731 mm long (620 mm SVL) *Heterodon platirhinos* was captured 5 km SE of South Roxana, Madison Co., Illinois, USA (NE1/4, Sec. 19, T4N, R8W). The snake regurgitated a partially digested male Fowler's toad (*Bufo woodhousii fowleri*) that weighed 24.9 g. A number of nematodes were observed on and in the open body cavity of the toad at the time of collection. The toad and nematodes were preserved in the field (Illinois Natural History Survey, INHS 14508). The snake was marked and released.

The nematodes were identified in the laboratory as *Physaloptera variegata*. This species was originally described from the stomachs of Florida *Coluber constrictor* (Reiber et al. 1940. Lloydia 3:125–144). They also reported the species from *Thamnophis sirtalis* from Florida and *Lampropeltis getula nigra* from Georgia (Reiber et al., *op. cit.*). Mawson (1956. Can. J. Zool. 34:75–76) reported *P. variegata* from *C. constrictor*, *Heterodon platirhinos*, and *Ophisaurus ventralis*, all from Georgia. Our finding confirms the association between *P. variegata* and *H. platirhinos* and is a new locality record for the nematode.

Physaloptera variegata has never been reported from an amphibian host. We examined the stomachs, intestines, and lungs under 7X magnification for 80 *Bufo woodhousii fowleri* collected in 1999 from this site. Twelve (15%) toads contained from 1 to 28 *Rhabdias bufonis*, a nematode previously reported from *B. w. fowleri* (Goldberg et al. 1996. Great Basin Nat. 56:369–374), but no toad contained *P. variegata* . We thus found no evidence that the toad acted as a vector for *P. variegata*. Rather it seems more likely that the association between the toad and *P. variegata* was coincidental.

LAMPROPELTIS PYROMELANA (Mountain Kingsnake). **MORTALITY**. Reports of squirrels defensively attacking snakes are not uncommon (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. Univ. of California Press, Berkeley. 1533 pp.; Coss and Owings 1989. Natural History 98[5]:30–35; Engeman 1994. Herpetol. Rev. 25:125). Less frequently, squirrels have been seen preying on snakes or eating freshly killed snakes (Harriot 1940. J. Mamm. 21:92; Wistrand 1971. Am. Midl. Nat. 88:511–512; Halpin 1983. Am. Midl. Nat. 109:50–54; Cobb and Peterson 1999. Herpetol. Rev. 30:45–46).

On 21 April 1999 at 1450 h one of us (BLC) observed a rock squirrel, *Spermophilus variegatus*, attack a *Lampropeltis pyromelana* (85 g, 675 mm SVL) amid a Gambel oak (*Quercus gambelli*) woodland at ca. 2255 m in the Animas Mountains, Hidalgo Co., New Mexico, USA. The squirrel had paused on a rock when it abruptly bounded over to a patch of dead leaves and appeared to aggressively root around in the leaf pile. With the aid of binoculars it became apparent the squirrel was attacking a *L. pyromelana*. The squirrel was frightened off and the kingsnake collected. The snake sustained extensive injuries from the rodent's incisors. These included 8–9 punctures of the body wall, several with emergent viscera. One wound appears to have seriously damaged the snake's spine. The snake was cold to the touch, although the air temperature (1.5 m above the surface) was 22.5°C. The snake was held for observation, discovered dead the next morning, and subsequently deposited in the Museum of Southwestern Biology, University of New Mexico (MSB 61278). This observation was made in the course of an ongoing mark-recapture investigation of the ecology of this montane snake community. The male *L. pyromelana* was previously captured in the same location on 4 October 1998 at which time it weighed 87 g.

Published accounts of *S. variegatus* encounters with snakes are limited to *Pituophis melanoleucas* and involve a very aggressive attack by the squirrel, with the squirrel kicking debris and/or biting the snake, possibly in defense of young (Haywood and Harris 1971. Texas J. Sci. 22: 427; Knickerbocker 1988. Arizona Highways 64[9]:12–15). In our area *S. variegatus* does not give birth to young until late May at the earliest, and most give birth in June (Ortega 1990. J. Mamm. 71:448–457). In this case, the squirrel clearly initiated an agressive encounter that was not in defense of nestlings. For this reason, and because *S. variegatus* occasionally takes other live vertebrate prey (Hoffmeister 1986. The Mammals of Arizona. University of Arizona Press, Tucson, Arizona. 602 pp., and citations therein) we believe the squirrel was preying on the snake. Prior to this report, the sole published predator of *L. pyromelana* was the Mexican spotted owl, *Strix occidentalis lucida* (Duncan 1992. Herpetol. Rev. 23:81).

Submitted by **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA, and **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA (e-mail: holycow@asu.edu).

LAMPROPHIS FULIGINOSUS (Brown House Snake). **PREDATION**. A number of invertebrates are reported to prey on reptiles (for reviews see Greene 1988. *In* Gans and Huey (eds.), Biology of the Reptilia, vol. 16, Ecology B. pp. 1–152. Alan R. Liss, New York; McCormick and Polis 1982. Biol. Rev. 57:29–58), but no published accounts of spider predation on snakes are known to this author. I report below on two separate occurrences of predation by a geometrid button spider (*Latrodectus geometricus*) on juvenile (less than a year old) brown house snakes.

On 25 March 1999, I observed a *Lamprophis fuliginosus* entangled in a geometrid button spider web. The incident took place in Pretoria North, Gauteng Province, South Africa. The posterior portion of the snake was caught in the web, less than 30 cm above the ground, while the anterior half rested on the ground. The snake had two puncture marks two-thirds of the way down its body. Just posterior to these marks were further bite marks from where the spider was feeding. The posterior half of the snake was paralyzed.

In the other observation, also in Pretoria but recorded fifteen months earlier, the situation was similar, except that the anterior half of the snake was entangled in the web about 20 cm above the ground. The snake had two puncture marks midway along its body from where the spider was feeding. The snake was unable to free itself, since it was almost completely paralyzed.

In the highveld (typical savanna/grassland habitat), both geometrid button spiders and brown house snakes occur in abundance. Wulf Haacke (pers. comm.), herpetologist at the Transvaal Museum of Natural History, once observed predatory behavior of the geometrid button spider on a juvenile herald snake (*Crotaphopeltis hotamboeia*). In these situations, I believe that spider predation on juvenile snakes is opportunistic. Neither the brown house snake nor herald snake is normally a climber and they therefore probably became entangled in one of the catching

cords hanging from the web, resulting in part of its body being pulled up into the web. From its aerial scaffolding, the geometrid button spider spins vertical strands of exceptionally strong, elastic silk which is sticky near the bottom, where it is anchored lightly to the ground. When an animal touches a strand, the strand comes unstuck from the ground and entangles the prey, at the same time drawing the prey upward (see Lamoral 1968. Ann. Natal Mus. 20:1–14).

I thank Wulf Haacke for comments on this note, and Martin Whiting for the identification of *Lamprophis fuliginosus*.

LYSTROPHIS DORBIGNYI (Nariguda). **DIET**. The occurrence of reptile eggs in the diet of snakes is known in only a few species of colubrids, among them *Cemophora coccinea* (Dickson 1948. Copeia 1948:216–217; Minton and Bechtel 1958. Copeia 1958:47; Palmer and Tregembo 1970. Herpetologica 26:300–302), *Boiga trigonata* (Greene 1989. Proc. California Acad. Sci. 46:193–207), and *Siphlophis pulcher* (Sazima and Argôlo 1994. Herpetol. Rev. 25:126). Most of the snakes of the tribe Xenodontini have frogs as primary prey, whereas eggs have not been reported (Cadle and Greene 1993. *In* Ricklefs and Schluter [eds.], Species Diversity in Ecological Communities: Historical and Geographical Perspectives, pp. 281–293. Univ. of Chicago Press, Chicago, Illinois.). *Lystrophis dorbignyi* is a diurnal, terrestrial to semifossorial South American xenodontine known to feed on anurans and small lizards (Gudynas 1979. ASRA Journal 1[2]:24–33; Lema et al. 1973. Iheringia, Sér. Divulg. 3:19–33; Orejas-Miranda 1966. Copeia 1966:193–205; pers. obs.). Coleopterans were also reported (Orejas-Miranda, op. cit.), but after an examination of several stomachs containing coleopteran elytra consistently associated with anuran remains, we regard these as having been ingested secondarily.

Here we report on two instances of *L. dorbignyi* feeding on reptilian eggs, one observation being made in captivity and another under natural conditions. Both snakes are from the Municipality of Balneário Pinhal, State of Rio Grande do Sul (30°21'S, 50°17'W). Vouchers are housed in the Museu de Ciências e Tecnologia da PUCRS, Porto Alegre, Brazil (MCP 5180, 5563; MCPAN 759).

One adult female (SVL = 440 mm) captured on 9 November 1996 was kept in a terrarium with sand covering its floor. On 13 December 1996 the snake laid four eggs and swallowed them 17 days later. Examination of the stomach contents of an adult male (SVL = 326 mm) revealed four almost entire eggshells measuring about 15 x 10 mm. The shells show leathery texture and size compatible with that of the lizard *Liolaemus occipitalis* (Verrastro, pers. com.), the most frequent species of lizard that is sympatric with *L. dorbignyi* in the area of study (pers. obs.). There were no remains of other stomach contents, eliminating the possibility of the eggshells being secondary prey.

We thank Márcio Borges Martins, Ronaldo Fernandes, and Robert A. Thomas for reviewing this note, and CAPES for the fellowship (RBO).

MEHELYA CROSSI (West African File Snake). **DIET**. The diet of African file snakes (*Mehelya* spp.) is poorly known but is generally described as consisting of lizards and snakes, and more rarely anurans (e.g., see Cansdale. 1961. West African Snakes. Longmans, London, pp. 72; Wilson. 1965. Puku 3:149–170; Villiers. 1975. Les Serpents de l' Ouest Africain. IFAN, Dakar, pp. 195; Shine et al. 1996. J. Zool. London 240:327–340). During a long-term study on the ecology of forest snakes in southern Nigeria (e.g., see Luiselli et al. 2000. Can. J. Zool. 78:191–198), we had the opportunity to assess the diet of *Mehelya crossi* and contrast our data with published information on this species and other congeners.

Collections were made between September 1996 and May 2000, from several localities of southeastern Nigeria, situated in the territories of central and eastern Niger Delta (Bayelsa and Rivers states), in Anambra State, Enugu State, Abia State, Akwa-Ibom State, Imo State, and Cross River State. The sites where file snakes were found were characterized by patches of rainforest interspersed among large plantations (yam, cassava, cocoa, pineapple, banana, plantain, oil palm, etc). The study region has a typical tropical climate, with a wet season occurring from May to September, and a dry season from October to April.

Free-ranging snakes were constrained and forced to regurgitate by abdominal palpation. Fecal pellets were also collected and later analyzed in the laboratory. In addition, specimens found dead (roadkilled, macheted by farmers, or preserved in collections of local institutions, cf. Luiselli et al. 2000, *op. cit.*) were dissected. Vouchers are deposited in the herpetological collections of the Department of Biological Sciences, Rivers State University of Science and Technology, Port Harcourt, of the Cross River National Park, Akampka, and of the Institute Demetra, Rome.

We examined the stomachs of 31 *Mehelya crossi* specimens and found only five prey items. Although 84% of these specimens had empty stomachs, prey remains were identified from the feces of seven other specimens. Contrary to published information (e.g., see Cansdale 1961, *op. cit.*), we found that three of the five prey items were endothermic organisms. These prey items included a juvenile *Lemniscomys* sp., an adult *Mus minutoides* (= *musculoides*), and a *Crocidura nigeriae*. The remaining two were one *Agama agama* and one *Bufo* sp. (this latter record has been already presented in Luiselli et al. 1998. J. Zool. London 246:125–133). From feces, we identified the following prey remains: *Agama agama* (in three different specimens), Scincidae sp. (in two specimens), Gekkonidae sp. (in one specimen), and an unidentified rodent (in one specimen). The remains of the *Lemniscomys* and *Crocidura* came from specimens that were captured in cassava plantations (at Ahoada and Eket, respectively), whereas the *Mus musculoides* was ingested by a snake from a secondary swamp forest near Calabar. Lizard remains were also found in snakes from suburban habitats (i.e., *Agama* specimens were eaten by snakes captured at Port Harcourt, Ahoada, Uyo, and Calabar), but also in mature forest (Orashi River forest, and Taylor Creek Forest Reserve). The remains of the *Bufo* came from a specimen inhabiting a riverine forest along the Kwa-Ibo River. Thus, there was no

apparent difference in the prey items of snakes inhabiting either altered or forest habitats. Snakes from both habitat types fed on mammals and reptiles.

This note, although preliminary, demonstrates that mammalian prey should be considered approximately as important as reptilian prey for *Mehelya crossi*, thus negating the general opinion that *Mehelya* species prey only on ectothermic animals. In this regard, it is noteworthy that a rodent prey item (*Rattus rattus*) was taken by another *Mehelya crossi* specimen from southeastern Nigeria (Butler and Reid 1990. Niger. Field 55:19–40).

We thank E.N.I.-Agip Environmental Department, Aquater S.p.A., Snamprogetti S.p.A., T.S.K.J. Nigeria Ltd., Ecosystem s.r.l., Demetra s.r.l., F.I.Z.V., and Chelonian Research Foundation (Linnaeus Fund), for having financially supported parts of our long-term research in Nigeria. Massimo Capula and Francesco M. Angelici critically commented on previous drafts of this manuscript and gave important data input. Several colleagues helped us in the field, and Francesco M. Angelici identified the mammalian prey eaten by snakes. Zena Tooze improved the English grammar. Authors are in alphabetical order.

OPHEODRYS AESTIVUS (Rough Green Snake). **HIBERNACULUM**. Little is known about the hibernaculum requirements of *Opheodrys aestivus*. In February 1985 D. B. McCallum, Jr., and I extracted a single *O. aestivus* from a crayfish burrow at the top of a snow-covered, 2 m high earthen levee. The snake's sex and size were not recorded. No crayfish were observed in the burrow. The lake which the levee originally formed was drained in the early 1970's (exact date unavailable). The remaining small stream, about 10 cm deep, did not inundate the levee from August 1978 through May 2000 and probably had not since the pond was drained. The burrow was ca. 0.5 m deep and had a typical mud-clogged chimney about 10–15 cm high. The snake was held in captivity until April and then released near its capture site in Detering Hills Subdivision, approximately 3 km east and 0.5 km north of the junction of Interstate 55/70 and State Route 159, and 2 km south of Maryville, Madison Co., Illinois, USA. I thank Mike Plummer and Stan Trauth for feedback and encouragment to submit this observation.

PHILOTHAMNUS HETERODERMUS (NCN). **REPRODUCTION**. The reproductive biology of free-ranging *Philothamnus heterodermus* is poorly known, although this species is widely distributed throughout the rainforest region of West Africa (e.g., see Villiers 1975. Les Serpents de l' Ouest Africain. IFAN, Dakar, 195 pp.; Hughes. 1983. Bonn. Zool. Beitr. 34:311–355; Hughes. 1985. Proc. Int. Symp. Afr. Vert. Bonn, pp. 511–530). In this note we provide data to clarify the reproductive seasonality of this snake from the wild.

Four gravid females were collected in lowland swamp forests of the eastern Niger Delta (Port Harcourt, Rivers State). Additionally, a newborn male was collected from the high forest of Iko Esai, ca. 70 km north of Calabar (Cross River State). The four gravid females were collected on 11 October 1996 (total length [TL] = 84 cm, 5 eggs, mean egg size = 24 x 9 mm), 15 October 1998 (TL = 81.2 cm, 4 eggs, mean egg size = 22 x 9 mm), 17 November 1999 (TL = 86.3 cm, 5 eggs, mean egg size = 24.2 x 10 mm), and 1 December 1999 (TL = 76.1 cm, 3 eggs, mean egg size = 21.4 x 8 mm). The newborn male, with a fully-evident umbilical scar, was captured on 11 April 2000, and measured 17.4 cm SVL and 6.1 cm tail length. These specimens are deposited in the herpetological collection of the Institute Demetra (Aquater S.p.A., Rome). The date of capture for two additional gravid females is unknown. These two females measured 80.1 cm and 79.7 cm TL, and contained four eggs (mean egg size = 22.3 x 8.7 mm) and three eggs (mean egg size = 22.2 x 8.8 mm), respectively. Five additional adult females (between 70.5 and 83.7 cm TL) were captured in July, September (3 specimens) and October, but they were not gravid.

Maternal size (TL) significantly influenced the number of eggs produced ($r = 0.911$, $N = 6$, Y-intercept = -14.604; ANOVA $F = 19.556$, $df = 1,4$, $P = 0.011$), and also the mean egg size ($r = 0.94$, $N = 6$, Y-intercept = -1.839; ANOVA $F = 30.436$, $df = 1,4$, $P = 0.005$). At the same time, the number of eggs produced by a female and mean egg size were positively correlated ($r = 0.90$, $N = 6$, Y-intercept = 18.083; ANOVA $F = 17.087$, $df = 1,4$, $P = 0.014$), but this was an effect of the positive influence of maternal size on both variables.

The study region in southeastern Nigeria is tropical, with a pronounced wet season occurring from May to September. Although preliminary, our data clearly demonstrate that this species lays eggs during the dry season, and the eggs hatch during the interphase between end of the dry season and the onset of the wet season. The only other data on Nigerian specimens are from Butler and Reid (1990. Niger. Field 55:19–40). Based on evidence from two specimens, these authors suggested that eggs are laid at the end of the wet season, and hatch in the middle of the dry season or at the start of the wet season. In particular, they captured a newborn from Ibadan on 8 February, and a post-partum female from Calabar on 31 January. Thus, pooling all these data, it becomes obvious that *P. heterodermus* shows a well-marked seasonality in annual reproductive timing, with evident synchronized oviposition and egg hatching among females and among clutches. To better understand the benefits of hatching at the middle of the dry season or at the start of the wet season, it would be necessary to know the dietary habits of the newborns. Currently, we do not have enough data on the feeding behavior of this species; however, the single newborn specimen examined by us from Iko Esai forest north of Calabar had recently ingested a very small, newly metamorphosed toad (*Bufo* sp.).

PHILOTHAMNUS IRREGULARIS IRREGULARIS (Northern Green Snake). **REPRODUCTION**. Pitman (1974. A Guide to the Snakes of Uganda. Wheldon & Wesley, Ltd., Codicote, England. 290 pp.) records two communal nests of *Philothamnus irregularis irregularis*, and records egg dimensions that range from 25 x 14 to 43 x 18 mm. Pitman records that *P. irregularis battersbyi* lays 4–8 eggs in November–December or March–May, but does not provide clutch sizes for *P. i. irregularis*. Menzies (1966. Copeia 1966:169–179) reports a clutch size of six for one *P. i. irregularis*. To my knowledge, these are the only published reports on reproduction from this species. Here, I report observations on reproduction from four more *P. i. irregularis*, all of which were found in Area J of Yekepa, Nimba County, Liberia.

A *P. i. irregularis*, 84 cm total length (TL), found dead on 14 June 1987, contained five eggs, 38 x 10 mm. Another *P. i. irregularis*, 86 cm TL, killed on 14 July 1987, contained five eggs, each 23 mm long; egg width was not recorded. Two other *P. i. irregularis*, collected on 31 July 1987, contained eggs; clutch size is unknown for these two, as one had been badly smashed by an automobile, and the other was released before oviposition.

I thank Alfred and Torseh Yeanay and neighborhood children for finding the specimens recorded here.

Submitted by **PHIL SENTER**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: beccafaye@worldnet.att.net).

PSAMMOPHIS PHILLIPSII (Olive Grass Snake). **REPRODUCTION**. *Psammophis phillipsii* is a psammophiine colubrid snake from the West African forest. Few egg-related accounts of this species have been published. According to one account, eight large *P. phillipsii* were found in Liberia, "entwined together" in a hole in the ground which evidently was a communal nest, as it contained more than 52 eggs (Taylor and Weyer 1958. Univ. Kansas Sci. Bull. 38:1191–1229). Butler (1993. J. Herpetol. 27:144–148) records that a *P. phillipsii* from Nigeria laid 11 eggs on 12 January 1983; these hatched on 22 and 23 March 1983. Butler (*op.cit.*) also reports that a clutch of seven *P. phillipsii* eggs from Nigeria hatched on 3 March 1983, and that a clutch of nine from Liberia hatched on 10 April 1983. Broadley (1983. FitzSimons' Snakes of Southern Africa. Delta Books, Johannesburg. 376 pp.) states that "*P. phillipsii*" lays 10 to 30 eggs, with dimensions ranging from 28 x 10 mm to 40 x 20 mm, "in piles of dead leaves or some similar location in midsummer." However, this statement is based on observations of southern African populations which are now referred to *P. mossambicus* (Branch 1998. Field Guide to Snakes and Other Reptiles of Southern Africa. Ralph Curtis Books, Sanibel Island, Florida. 399 pp.).

Here, I report egg-related data from two Liberian specimens of *P. phillipsii* (*sensu stricto*). These data support the conclusions of Butler (*op. cit.*), based on preserved specimens, that *P. phillipsii* oviposits in the dry season. On 6 January 1988, I collected a gravid, 104-cm *P. phillipsii* from the area of Congotown in Monrovia, Liberia. The specimen had been mortally wounded by humans. Dissection revealed that the snake was gravid with 10 eggs, 31 mm x 17 mm. On 6 January 1989, I collected a live, 114-cm *P. phillipsii* from the grounds of the American Cooperative School in the area of Singkor, in Monrovia, Liberia. This was the individual whose bite was recorded by Senter (1998. Herpetol. Rev. 29:216–217). The snake laid one egg on the date of capture, a second egg on 7 January, and nine more eggs on 8 January. The Singkor specimen was released on 12 January 1989. Its eggs were roughly the same size as those in the oviducts of the snake from Congotown.

I thank John Anderson of the American Cooperative School for locating the Singkor specimen. I thank Jayne Cawthon for transporting it to Congotown for me. I thank unidentified individuals for calling the Congotown specimen to my attention.

Submitted by **PHIL SENTER**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA (e-mail: beccafaye@worldnet.att.net).

SORDELLINA PUNCTATA (NCN). **REPRODUCTION**. The xenodontine colubrid *Sordellina punctata* occurs mainly in the Atlantic Forest domain in southeastern Brazil (Hoge and Romano 1976/77. Mem. Inst. Butantan 40/41:63–70) and is rare in herpetological collections. This is an elusive aquatic snake whose reproductive characteristics have not been reported. Here I present data on the reproductive cycle, fecundity, and mode of reproduction, based upon dissection of 12 specimens housed in the collection of the Instituto Butantan in São Paulo (IB).

An adult female (IB 25130, 360 mm SVL, 65 mm tail length) collected in September contained four vitellogenic follicles. Two females (IB 22313, 530 mm SVL, 75 mm tail length; and IB 46054, 495 mm SVL, 80 mm tail length) collected in October contained seven vitellogenic follicles each. A fourth snake (IB 10464, 385 mm SVL, 70 mm tail length) collected in February contained three eggs in the oviducts. The size of females and number of follicles or eggs indicate that clutch size appears to be related to maternal body size, as occurs in most snakes (Shine 1994. Copeia 1994:851–867). An additional eight females collected throughout the year contained no vitellogenic follicles or eggs. One presumed hatchling (IB 57875, 180 mm SVL, 30 mm tail length) was collected in June. Thus, the reproductive cycle of *S. punctata* seems to be seasonal; vitellogenesis and ovipositon occurs in the rainy season (October–March), and hatching occurs at the onset of the dry season

(May–June). The data presented here indicate that *S. punctata* is an oviparous species, an unusual reproductive mode for an aquatic snake as most aquatic snakes are viviparous (Shine 1983. *In* Biology of the Reptilia. Vol 15. Development B. C. Gans and F. Billet [[eds.], pp. 605–694. John Wiley and Sons, New York.). However, some aquatic xenodontines such as *Helicops angulatus*, *H. hagmanni*, and *Pseudoeryx plicatilis* present both viviparous and oviparous reproductive modes (Cunha and Nascimento 1981. Bol. Mus. Par. Emilio Goeldi 109:1–20). Therefore, additional data are needed to assess whether *S. punctata* follows this dual pattern. I thank I. Sazima for reviewing this manuscript.

THAMNOPHIS SIRTALIS PARIETALIS (Red-sided Gartersnake) **MALE-MALE COPULATION.** Although male mimicry of females occurs in many animal species (Burley 1982. *In* Alexander and Tinkle [eds.], Natural Selection and Social Behavior, pp. 121–137. Chiron, New York), most cases of male-male courtship do not appear to progress to actual copulation (Bagemihl 1999. Biological Exuberance: Animal Homosexuality and Natural Diversity. St. Martin's Press, New York. 751 pp.). In reptiles, female mimicry apparently leading to homosexual copulation has been reported in one lizard species (*Anolis garmani*, Trivers 1976. Evolution 30:253–269), but with little detailed information. The only well-studied example of female mimicry in reptiles involves red-sided gartersnakes, *Thamnophis sirtalis parietalis*, that overwinter in large communal dens in Manitoba. The snakes court and mate as they emerge in spring. Courting males recognize the sex of other snakes based primarily on lipids in the skin (Mason 1992. *In* Gans and Crews [eds.], Biology of the Reptilia, Volume 18. Hormones, Brains and Behavior, pp. 114–228. Univ. Chicago Press, Chicago). In the Manitoba dens, some males ("she-males") produce female-like pheromones, and thus attract substantial courtship from other males (Mason and Crews 1985. Nature 316:59–60; Shine et al. 2000. Anim. Behav. 59:349–359). In this note, we provide the first example of apparent male-male copulation.

On 17 May 1999, we were conducting ecological research at a large snake den in a gravel quarry 1.5 km N of Inwood, 0.5 km E of Highway 17 (50°31.58'N 97°29.71'W), in southern Manitoba, Canada. While collecting she-males for behavioral trials, we found a male (47.7 cm SVL, 13.2 cm tail length, 33.0 g) being actively courted by four other males. When the she-male was collected, we noticed that it was bleeding from the cloacal area, and that the snake's body contained a hard object a few centimetres anterior to the cloaca. We palpated this object posteriorly and out of the snake's cloaca. It was a gelatinous mating plug (Fig. 1), identical to those deposited in heterosexual matings by this species. The plug weighed 0.035 g, within the size range of plugs from male-female matings (Shine et al., unpubl. data). The she-male showed no overt physical peculiarities. Its sex was confirmed by manual eversion of hemipenes (Fig. 1). The snake and copulatory plug were preserved and deposited in the University of Michigan Museum of Zoology (UMMZ 224312).

Although we did not witness the actual copulation, the presence of the plug strongly suggests that this snake mated with another male. Such behavior must be extremely rare: we have never recorded it during the observation, capture, and handling of many hundreds of she-males over many years. Most probably, the copulated male was moribund and unable to resist copulation. There is no need to invoke his co-operation in this event. Male gartersnakes at the dens frequently mate with dead and dying females, and with females with open wounds (usually, from pecks by crows) in their bodies (pers. obs.). A similar inability to resist mating attempts, because of poor health, may explain cases of interspecific copulations in captive snakes (Klauber 1956. Rattlesnakes: Their Habits, Life Histories and Influence on Mankind. Univ. California Press, Berkeley, California. 1533 pp.; Hardy 1998. Bull. Chicago Herpetol. Soc. 33:258–262).

Although the copulated male was not unusually slender-bodied (his mass relative to SVL was almost exactly average for males in this population; unpubl. data), other aspects support the idea that he was in poor health. He was limp-bodied when picked up and was covered in dirt; both of these traits characterize males that have emerged only recently from their overwinter den (Shine et al., unpubl. data). After we manually everted his hemipenes, he did not retract them. Indeed, they were still extruded when the snake was examined 24 h later, at the time he was killed and preserved.

Male-male courtship is frequently reported in captive snakes, but rarely progresses to copulation (Hardy 1998, *op. cit.*). To our knowledge, ours is the first record of male-male intromission by a free-ranging snake.

FIG. 1. Cloacal region of male gartersnake, showing everted hemipenes (to verify sex) and the cloacal plug partially everted from its vent.

This research was supported by the Australian Research Council (to RS) and by a National Science Foundation National Young Investigator Award (IBN-9357245), and the Whitehall Foundation (W95-04) to RTM. Research was conducted under the authority of Oregon State University Institutional Animal Care and Use Committee Protocol No. LAR-1848B. All research was conducted in accord with the U.S. Public Health Service 'Policy on Humane Care and Use of Laboratory Animals' and the National Institute of Health 'Guide to the Care and Use of Laboratory Animals.'

WILMSLOW** and **RICHARD SHINE**, Biological Sciences A08, The University of Sydney, NSW 2006 Australia (e-mail: rics@bio.usyd.edu.au).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother 2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. SSAR Herpetol. Circ. 29:1–82; for Mexico as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*. Herpetol. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: Joseph T. Collins (USA & Canadian records only), Kansas Biological Survey, 2041 Constant Avenue, Lawrence, Kansas 66047, USA; Jerry D. Johnson (Mexico and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; Hidetoshi Ota (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or Gustavo J. Scrocchi (South American records), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina. Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Marques, O. A. V., and G. Puorto. 1996. Geographic Distribution. *Chironius laevicollis*. Herpetol. Rev. 27:212.

GYMNOPHIONA

SIPHONOPS PAULENSIS (Boettger's Caecilian). BRAZIL: MINAS GERAIS: Uberlândia Municipality (18°59'S, 48°18'W). 13 February 1989. Anselmo de Oliveira. Coleção Zoológica da Universidade Federal de Uberlândia, Ariovaldo A. Giaretta 2025. Verified by Ariovaldo A. Giaretta. First record of species and genus for Cerrado region, where the only gymnophionid taxon previously known was *Cthonerpeton perisodus* (Duellman 1999. *In* Duellman [ed.], Patterns of Distribution of Amphibians. A Global Perspective, pp. 255–328. Johns Hopkins Univ. Press). This species also is known from the municipality of Brasília (ca. 424 km NW Uberlândia). Extends range to NW Brazil, beyond the Atlantic forest domain (ca. 600 km).

Submitted by **MARCELO N. DE C. KOKUBUM** and **MARCELO MENIN**, Instituto de Biologia, Universidade Federal de Uberlândia, 38400-902, Uberlândia, Minas Gerais, Brazil.

CAUDATA

AMBYSTOMA PLATINEUM (Silvery Salamander). USA: INDIANA: Randolph Co: Davis Woods, a 50 acre woodlot owned by Purdue University (40°15'30"N, 85°90'30"W). 10 April 2000. Priya Nanjappa. Vertebrate Zoology Section, Milwaukee Public Museum (MPM P-698). Verified by C. A. Phillips. Specimen had SVL of 89 mm and an internarial distance of 4.5 mm, characteristic of *Ambystoma platineum* (Uzzell 1964, Copeia 1964:247–300). New county record (Minton *In Press*, Amphibians and Reptiles of Indiana. Second Ed.).

Submitted by **PRIYA NANJAPPA** and **LAURA (LEININGER) BLACKBURN**, Muncie Center for Medical Education, Ball State University, Muncie, Indiana 47306, USA.

ENSATINA ESCHSCHOLTZII (Ensatina) USA: WASHINGTON: Kittitas Co: NE 1/4 Sec. 10, T19N, R14E, South Cle Elum Ridge, near Granite Creek, Wenatchee National Forest, 1000 m elev. 9 September 2000. James W. Baugh. MVZ 230987. Verified by David B. Wake. Mature adult (SVL = 70 mm; TL = 117 mm). Locality represents not only a new county record, but also extends range for the species eastward by a distance of ca. 30 km (Washington Department of Fish and Wildlife Herptile Data Base) and is the first recorded occurrence of this species east of the Cascade crest in the state of Washington (Leonard et al. 1983, Amphibians of Washington and Oregon. Publ. Seattle Audubon Society, Washington. 168 pp.; Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp.).

Submitted by **DAVID M. DARDA**, Department of Biological Sciences, Central Washington University, Ellensburg, Washington 98926, USA (e-mail: dardad@cwu.edu), and **JAMES W. BAUGH** and **PATRICIA A. GARVEY-DARDA**, Cle Elum Ranger District, Wenatchee National Forest, Cle Elum, Washington 98922, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: WISCONSIN: Door Co: Toft Point State Natural Area (45°04'23.5"N, 87°05'48.8"W). 4 September 2000. Steven J. Price and Russell D. Japuntich. Richter Museum of Natural History (RMNH 513-R). Verified by T. C. Erdman. First county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Mus., Milwaukee Wisconsin. 87 pp.).

Submitted by **STEVEN J. PRICE**, Department of Natural and Applied Sciences, University of Wisconsin at Green Bay, Green Bay, Wisconsin 54311, USA (e-mail: pricsj07@uwgb.edu).

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: WISCONSIN: Juneau Co: Camp Douglas, Castle Rock Wayside Park. 23 August 1999. Sharon C. Rossman and Douglas A. Rossman. Milwaukee Public Museum Photo Voucher 694. Verified by Gary S. Casper. First record for county (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Museum. 87 pp.). Specimen

was crawling on surface (leaf mulch and sandy soil) adjacent to wooden tie used to stabilize the slope. It had rained a short time earlier and the substrate was quite damp at 1100 h under an overcast sky.

Submitted by **SHARON C. ROSSMAN** and **DOUGLAS A. ROSSMAN**, Department of Biology, Luther College, Decorah, Iowa 52101, USA.

OEDIPINA TAYLORI. HONDURAS: FRANCISCO MORAZÁN: Sabana Grande (13°48'N, 87°16'W), 980 m elev. November 1998. D. M. Rivera. UNAH 3971. Verified by L. D. Wilson. First record for country; closest reported locality is from the vicinity of the city of San Salvador, El Salvador (Brame 1986, J. Herpetol. 2:1–64) about 210 km airline WSW of the Honduran locality.

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157, USA, **GUSTAVO A. CRUZ**, Departamento de Biología, Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, and **DELMY M. RIVERA**, Departamento de Biología, Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras.

ANURA

AMOLOPS LARUTENSIS (Larut Torrent Frog). MALAYSIA: PENINSULAR MALAYSIA: Johor: Bekok Forest, Sungai Bantang, cascades over boulders (1°20'N, 103°10'E, 125 m elev.). 27 December 1996. Tzi Ming Leong. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.3470a, SVL 28.6 mm; ZRC.1.3470b, SVL 43.1 mm). Verified by Kelvin K. P. Lim. Represents southernmost extremity of its range in the peninsula. New state record, in addition to Kelantan, Perak, Selangor, Terengganu, and Pahang (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg).

ELEUTHERODACTYLUS JOHNSTONEI (Johnstone's Frog). VENEZUELA: MONAGAS: Caripe, elev. ca. 800 m, found calling in gardens of private residences and on streetside vegetation surrounding the Hotel Venezia near the city center. 13 September 2000. Hinrich Kaiser and L. Lee Grismer, La Sierra University Photographic Collection (LSUPC F-555). Verified by John E. Simmons. Extends the range of this highly adaptable colonizer 75 km airline SE of the coastal city of Cumaná, where the species had been introduced from Caracas in 1967 (Hardy and Harris 1979, Bull. Maryland Herpetol. Soc. 15:124–133). Caripe has been developed into a tourist access point for the famous Cueva del Guácharo in recent years, and the need for a more appealing city appearance has probably facilitated the transport of stowaway *E. johnstonei* on ornamental plants, as has occurred in Venezuela and elsewhere (Gorzula 1989, Herpetol. Rev. 20:56; Kaiser 1997, Biodivers. Conserv. 6:1391–1407). Caripe is the locality for *E. johnstonei* with the greatest elevation outside the Venezuelan Andes; Maturín, elev. ca. 200 m, found calling in empty inner city lots on metal and wood debris and on weeds adjacent to the Hotel Colonial. 17 September 2000. Hinrich Kaiser and L. Lee Grismer. LSUPC F-556. Verified by John E. Simmons. Extends the range of the species 65 km airline SE Caripe, or 165 km north Ciudad Guayana (erroneously reported as Ciudad Guayhana by Gorzula, *op. cit.*). HK also saw the species in the grounds of the Hotel Puerto Viejo in the coastal town of Maiquetía (Distrito Federal), the location of Simon Bolívar International Airport, and it has been reliably reported from the new "Las Casas Botes" development in Puerto La Cruz, Anzoátegui State (Oscar Palis, pers. comm.). The overall distribution pattern of *E. johnstonei* in Venezuela continues to be restricted to population centers of significance along major roads. This leads us to conclude that the species currently expands its range in Venezuela exclusively through human activity.

Submitted by **HINRICH KAISER** (e-mail: hkaiser@lasierra.edu) and **L. LEE GRISMER** (e-mail: lgrismer@lasierra.edu), Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

HYLORINA SYLVATICA. ARGENTINA: CHUBUT: Departamento Futaleufú: Los Alerces National Park, 1 km W Lago del Medio, 42°50'S, 71°52'5"W, ca. 550 m elev. 21 April 1982. Salvador Vellido. Adult. Fundación Miguel Lillo, Tucumán, Argentina (FML 09744). Verified by Néstor G. Basso. Specimen was found on a vertical tree trunk ca. 1 m high in a temperate rain forest of *Nothofagus* spp., where the understory was dominated by the bamboo *Chusquea culeou*; close to this site there are extensive wetlands created by overflow from the Río Stange. This species inhabits austral forests of Chile and Argentina with a narrow distribution along the eastern slopes of the Andes. In Chile, it is distributed from the western slopes of the Cordillera de Nahuelbuta (37°18'S, 73°17'W) (Ortiz et al. 1990, Comun. Mus. Reg. Concepción 4:31–43) to Laguna San Rafael (46°40'S, 74°00'W) (Díaz-Páez and Williams 1999, Res. V Congr. Latinoamericano de Herpetología. Publ. Extra Museo Nacional de Historia Natural, Montevideo, Uruguay 50:54). In Argentina, it has thus far been recorded only for the Nahuel Huapi National Park in southern Neuquén Province and in northern Río Negro Province (40°47' to 41°11'S) (Vellard 1947, Acta Zool. lilloana 4:145–153; Gallardo 1962, Rev. Mus. Argentina Cienc. Nat., Bs. As. Zoología 8[10]:113–122; Barrio and Rinaldi de Chieri 1971, Physis 30[81]:673–685). This voucher represents a new record for the province of Chubut, extends the known range of species in Argentina ca. 183 km air line S from previously southernmost vouchered citation at the base of Mt. Tronador close to the Vaca Overa glacier, Nahuel Huapi National Park (Vellard, *op. cit.*), and decreases the distributional hiatus between the southern distribution limit of this species in Chile and that in Argentina. The area where the specimen was found is also inhabited by *Pleurodema thaul*, *Eupsophus calcaratus*, and *Alsodes australis*.

Submitted by **SALVADOR VELLIDO**, Admistración de Parques Nacionales, Casilla de Correo 64, 4107 Yerba Buena, Provincia de Tucumán, Argentina, and **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, R 8400 FRF Bariloche, Provincia de Río Negro, Argentina.

LALIOSTOMA LABROSUM (formerly *Tomopterna labrosa*). MADAGASCAR: ANTSIRANANA: Montagne des Français, 20 m elev., 12°18'44"S, 49°20'17"E. 13–16 March 2000. M. Vences, F. Glaw, and K. Schmidt. Zoologische Staatssammlung München (ZSM 500–501/2000) and Université d'Antananarivo, Département de Biologie Animale (UADBA cat. nos. pending, four specimens). Verified by Wolfgang Böhme. First record from the biogeographic region of northern Madagascar. Extends range 185 km northwards (Glaw and Vences 1992, A Fieldguide to the Amphibians and Reptiles of Madagascar. Köln Press. 331 pp.). Confirms older dubious records (Mocquard 1895, Bull. Soc. Philom. Paris, ser. 8, 7:112–136; Guibé 1978, Bonn. Zool. Monogr. 11) which were not accepted by Blommers-Schlösser and Blanc (1991, Faune de Madagascar 75:1–379) and subsequent authors.

Submitted by **MIGUEL VENCES**, Muséum national d'Histoire naturelle, Laboratoire des Reptiles et Amphibiens, 25 rue Cuvier, F-75005 Paris, France, and **FRANK GLAW**, Zoologische Staatssammlung, Münchhausenstr. 21, D-81247 München, Germany.

LEPTODACTYLUS COLOMBIENSIS: VENEZUELA: ESTADO TACHIRA: Río Doradas, 28 km South of Pregonero, 630 m. 5 October 1995. Collected by Curso Taxonomía Vertebrados B-95. Colección de Vertebrados, Universidad de los Andes, Facultad de Ciencias (CVULA 5638–42). Verified by Amelia Díaz de Pascual. First country record and northernmost for the species (ca. 7°50'N, 72°10'W). Previously known from flanks of northern Andes in Colombia (Heyer 1994, Smithson. Contr. Zool. 546). Presence of species in the Andean piedmont of Táchira is not surprising, because it is widely distributed through all slopes of the Andes in Colombia, and this locality is close to the Colombian border.

Submitted by **CÉSAR LUIS BARRIO AMORÓS**, Fundación Andígena, Apartado 210, 5101-A Mérida, Venezuela (e-mail: cesarlba@yahoo.com) and **ANDRES CHACON**, Facultad de Ciencias, Universidad de los Andes, Mérida, Venezuela (e-mail: trilobit@ciens.ula.ve).

MANNOPHRYNE COLLARIS. VENEZUELA: ESTADO MERIDA: Municipio Alberto Adriani (8°32'49"N, 71°34'58"W), ca. 10 km SSE El Vigía in submontane forest, 200 m elev. One male on 15 May 1999 and three females on 8 November 2000. Collector unknown. Colección de Vertebrados de la Universidad de Los Andes (CVULA-IV 6174, 6175, 6176, and 6177, respectively). Verified by Enrique La Marca. Species was previously known to occur only between 1100 and 1800 m. This is the westernmost record and the lowest locality known for the taxon, ca. 52 km W and 1000 m beneath the type locality, and suggests a wider distribution for this frog.

Submitted by **CARLOS GOTTBERG**, **PAOLO RAMONI-PERAZZI**, and **MARÍA JOSÉ PRADERIO**, Universidad de Los Andes, Facultad de Ciencias, Departamento de Biología, Mérida 5125, Venezuela (e-mail: gottberg@ciens.ula.ve).

MICROHYLA BORNEENSIS. MALAYSIA: PENINSULAR MALAYSIA: Selangor: Sungai Dusun lowland rainforest, forest floor (3°39'N, 101°18'E, 25 m elev.). 30 March 2000. Tzi Ming Leong. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.3865, adult male, SVL 17.2 mm). Verified by Kelvin K. P. Lim. New state record; known also from Terengganu and Pahang (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.; Manthey and Grossmann 1997, Amphibien and Reptilien Südostasiens. Natur und Tier—Verlag, Germany. 512 pp.). Outside of the peninsula, the species occurs in Singapore, southern Thailand, and Borneo (Brunei, Sabah, Sarawak) (Leong and Chou 1997, Raffles Bull. Zool. 45[1]:97–103).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg), and **ZAINAL ZAHARI BIN ZAINUDDIN**, Department of Wildlife and National Parks, Sungai Dusun, 44010 Kuala Kubu Bharu, Selangor, Malaysia.

MICROHYLA PALMIPES. MALAYSIA: PENINSULAR MALAYSIA: Terengganu: Sekayu waterfalls, forest floor (4°58'N, 102°58'E). 28 October 1998. Heok Hui Tan. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.3488, immature, SVL 12.8 mm). Verified by Kelvin K. P. Lim. New state record; known also from Pahang and Selangor (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp); northeastward range extension in the peninsula. Outside of the peninsula, the species occurs in Sumatra, Nias Island, Java and Bali (Iskandar 1998, The Amphibians of Java and Bali. LIPI Field Guide Series. xix + 117 pp).

Submitted by **TZI MING LEONG** (e-mail: scip0132@nus.edu.sg) and **HEOK HUI TAN** (e-mail: betta@mbox4.singnet.com.sg), Department of Biological Sciences, National University of Singapore, Singapore 119260.

RANA BARAMICA. MALAYSIA: PENINSULAR MALAYSIA: Kedah: Baling (5°41'N, 100°55'E). December 1938. Collector unknown. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.303, SVL 35.4 mm). Verified by Kelvin K. P. Lim. New state record; known also from Pahang, Selangor and Terengganu (Dring 1979, Bull. Brit. Mus. Nat. Hist. Zool. 34[5]:181–241; Manthey and Grossmann 1997, Amphibien and Reptilien Südostasiens. Natur und Tier—Verlag, Germany. 512 pp.). Represents northwestward extension of distribution in the peninsula.

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg).

RANA GLANDULOSA. MALAYSIA: PENINSULAR MALAYSIA: Pahang: Cameron Highlands, Tanah Rata, small stream feeding into main river at Parit waterfalls (4°28'N, 101°23'E, 1300 m elev.). 24–25 June 2000. Tzi Ming Leong et al. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.5157–5188, 32 larvae, Gosner stages 23–27, total lengths 8.5–33.0 mm; ZRC.1.5193, one larva, Gosner stage 41, total length 52.0 mm, bearing diagnostic adult characteristics). Verified by Kelvin K. P. Lim. New highland record for this species; known also from Gunong Bunga Buah and Fraser's Hill (Berry 1972, Herpetologica 28:338–346; Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.).

Submitted by **TZI MING LEONG** (e-mail: scip0132@nus.edu.sg) and **HEOK HUI TAN** (e-mail: betta@mbox4.singnet.com.sg), Department of Biological Sciences, National University of Singapore, Singapore 119260.

RANA HOSII. MALAYSIA: PENINSULAR MALAYSIA: Pahang: Cameron Highlands, Tanah Rata, Parit and Robinson waterfalls, (4°28'N, 101°23'E, 1300 m elev.). 5 May 2000. Heok Hui Tan. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.4093, immature, SVL 45.7 mm); 23–24 June 2000. Heok Hui Tan. (ZRC.1.4972, adult female with unpigmented ova, SVL 97.3 mm, fresh wt. 72 g; ZRC.1.4973, adult female with unpigmented ova, SVL 94.5 mm, fresh wt. 64 g; ZRC.1.4974, juvenile, SVL 26.3 mm). Verified by Kelvin K. P. Lim. Though often found in cascade/waterfall habitat almost throughout the country (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.), the species has not been previously recorded from this particular montane locality (Smedley 1931, Bull. Raffles Mus. 6:105–123).

Submitted by **TZI MING LEONG** (e-mail: scip0132@nus.edu.sg) and **HEOK HUI TAN** (e-mail: betta@mbox4.singnet.com.sg), Department of Biological Sciences, National University of Singapore, Singapore 119260.

RANA PALUSTRIS (Pickerel Frog). USA: MICHIGAN: Tuscola Co: Millington Road, 6.4 km E of SR-15. 12 June 1998. G. M. Fox and Brian Yang. UMMZ 222703. Verified by Arnold G. Kluge. First county record (Schaaf 1971, *Rana palustris*. Cat. Amer. Amphib. Rept. 117.1–117.4).

Submitted by **GLENN M. FOX**, Department of Biology and Division of Reptiles and Amphibians, University of Michigan Museum of Zoology, Ann Arbor, Michigan 48109-1079, USA (e-mail: foxg@umich.edu).

RANA SIGNATA. MALAYSIA: PENINSULAR MALAYSIA: Johor: Gunong Pulai foothills (1°36'N, 103°34'E, 25m elev.). 29 December 1988. Peter K. L. Ng. Raffles Museum of Biodiversity Research, Zoological Reference Collection (ZRC.1.1568, juvenile, SVL 14.4 mm). Verified by Kelvin K. P. Lim. Represents southernmost extremity of its range in the peninsula. Elsewhere, it is known to occur in southern Thailand, Borneo, and Sumatra. (Manthey and Grossmann 1997, Amphibien and Reptilien Südostasiens. Natur und Tier—Verlag, Germany. 512 pp.).

Submitted by **TZI MING LEONG** (e-mail: scip0132@nus.edu.sg) and **PETER K. L. NG** (e-mail: dbsngkl@nus.edu.sg), Department of Biological Sciences, National University of Singapore, Singapore 119260.

SCAPHIOPUS HOLBROOKII HOLBROOKII (Eastern Spadefoot). USA: NEW YORK: Saratoga Co: Wilton, Wilton Wildlife Preserve and Park (43°08'87"N, 73°41'47"W). 29 June 2000. New York State Museum (NYSM 3309). Verified by A. Breisch. Thirteen metamorphs (11–15 mm SVL) found in a drying pond covered with tussocks of *Scirpus* and *Cyperus* in pitch pine-scrub oak mixed forest over sand dunes. Reforested farmland. One photographed and preserved; 12 released. New county record and northern range extension from Albany Pine Bush Preserve, Albany County, of ca. 56 km (Stewart and Rossi 1981, American Midl. Nat. 106:282–292). This is the first record north of the Mohawk River.

Submitted by **DANIEL TIERNEY** and **MARGARET M. STEWART**, Department of Biological Sciences, State University of New York at Albany, Albany, New York 12222, USA.

TESTUDINES

APALONE SPINIFERA PALLIDA (Pallid Spiny Softshell). USA: TEXAS: Bowie Co: 9.7 km S Texarkana off State Line Road. 20 October 2000. Chris T. McAllister. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 25367). Verified by Stanley E. Trauth. New county record that helps fill a distributional gap in extreme northeastern Texas (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.). This turtle is known from across the state line in the Red River watershed of adjacent Miller County, Arkansas (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **CHRIS T. McALLISTER**, Department of Biology, Texas A&M University at Texarkana, Texarkana, Texas 75505, USA.

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: ARKANSAS: Arkansas Co: NW 1/4, Sec. 1, R2W, T7S, ca. 4 mi SE of Tichnor at jct. Wolf Bayou and Jacks Bay Road, White River National Wildlife Refuge. 18 August 2000. W. B. Blihovde. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 25342, skull only). Verified by Stan Trauth. Adult captured in trap. First record for county (Trauth, Robison and Plummer, ms. in prep.).

Submitted by **W. BOYD BLIHOVDE**, White River National Wildlife Refuge, P.O. Box 308, DeWitt, Arkansas 72042, USA, and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA.

TERRAPENE CAROLINA (Eastern Box Turtle). USA: INDIANA: Fayette Co: Mary Gray Bird Sanctuary (39°35'03"N, 85°133'44"W). 21 July 2000. Laura Blackburn. Milwaukee Public Museum (MPM P-697). Verified by M. J. Lannoo. One female was photgraphed among submergent vegetation along the edge of a semipermanent wetland. New county record (Minton *In Press*, Amphibians and Reptiles of Indiana. Second Ed.).

Submitted by **LAURA BLACKBURN** and **PRIYA NANJAPPA**, Muncie Center for Medical Education, Ball State University, Muncie, Indiana 47306, USA.

LACERTILIA

BASILISCUS BASILISCUS. VENEZUELA: ESTADO TRUJILLO: Hacienda Valerita, Sector Los Algodonales, Monay. 5 August 1983. R. Pérez. Colección de Vertebrados, Universidad de los Andes (CVULA 3481). First state record. ESTADO TÁCHIRA: Río Doradas, 600 m, 28 km S Pregonero. 6 October 1995. Collected by Curso Taxonomía de Vertebrados (B 95), adult male captured using a Victor's (mouse) trap (CVULA 5630); Río San Agatón, Doradas. 4 September 1984. Collected by Proyecto Faunístico Uribante-Caparo, juvenile (CVULA 4448). ESTADO ZULIA: Puerto Concha, Southern Lago de Maracaibo (several

specimens photographed in slide collection of Fundación Andígena: 257–258 and 266). All verified by Andrés Chacón. These reports confirm the continuous range of the species through the Maracaibo Lake basin (abundant populations were observed in diverse habitats such as mangrove, gallery forests, xerophytic riparian edges) and its penetration into the Andes along intramontane valleys up to an altitude of 1600 m. Conversely, it establishes the presence of the species on the SE slopes of the Andes toward the Orinoquian drainage. This has important biogeographic implications, but was not mentioned by La Marca and Milano (1995, Herpetol. Rev. 26:108). This may be the only known population for any member of the genus on the E side of the Andean chain.

Submitted by **CÉSAR LUIS BARRIO** and **ANDRÉS ORELLANA**, Fundación Andígena, Apartado Postal 210, 5101-A, Mérida, Venezuela (e-mail: cesarlba@yahoo.com and aorell@yahoo.com).

COSYMBOTUS CRASPEDOTUS. MALAYSIA: PENINSULAR MALAYSIA: Selangor: Kepong, lowland forest within FRIM (Forest Research Institute Malaysia) from upper trunk of tree (30 m above ground) at canopy walkway (3°14'N, 101°38'E, 300 m elev.). 21 September 2000. Tzi Ming Leong, Norsham Suhaina Yaakob and David K. L. Teo. Raffles Museum of Biodiversity Research, Zoological Reference Collection [ZRC.2.4821, juvenile, SVL 34.3 mm, total length 73.2 mm; one adult (total length ca. 150 mm) was also sighted at same locality, but not collected]. Verified by Kelvin K. P. Lim. New state record; known also from Perak and Penang Islands. Elsewhere, occurs in southern Thailand, Singapore, and Borneo (Manthey and Grossmann 1997, Amphibien and Reptilien Südostasiens. Natur und Tier—Verlag, Germany. 512 pp.).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg), and **NORSHAM SUHAINA YAAKOB** and **TERESA ONG**, Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur.

DIPLOLAEMUS DARWINI. ARGENTINA: CHUBUT: on Rt. 37, 26 km S of jct. Rt. 37 and Rt. 3, 45°41'S, 67°56'W, 640 m elev. 27 January 2000. Nora Ibargüengoytía and James A. Schulte II. Colección Centro Regional Universitario Bariloche, Universidad Nacional del Comahue, Provincia de Río Negro, Argentina (CH 25). Juvenile (SVL = 51.04 mm). Verified by J. M. Cei. Specimen was found in short scrub vegetation of Patagonian steppe habitat. The northernmost locality for this taxon is the NE corner of Santa Cruz near the border with Chubut (Cei 1986, Mon. IV Mus. Reg. Sci. Nat. Torino. 527 pp.); specimen represents the first record for Chubut Province and extends the known distribution of this species ca. 215 km north from any previously known locality. *Diplolaemus darwini* has been found in sympatry with *Diplolaemus bibroni* in Santa Cruz Province (Cei 1986, *op. cit.*), and this record extends the overlap in this distribution to Chubut Province.

Submitted by **NORA IBARGÜENGOYTÍA**, Centro Regional Universitario Bariloche, Universidad Nacional del Comahue, Provincia de Río Negro, Argentina, CONICET, and **JAMES A. SCHULTE II**, Campus Box 1137, Department of Biology, Washington University, St. Louis, Missouri 63130-4899, USA.

GEHYRA MUTILATA (Stump-Toed Gecko). MÉXICO: JALISCO: Guadalajara City, municipality of Zapopan, 1550 m. 8 August 2000. Paulino Ponce-Campos. Universidad Autónoma de Guadalajara, México (UAGM-R-427, photograph). Verified by H. M. Smith. Range extension; nearest previously known record was 191 km W at Puerto Vallarta (Smith and Grant 1958, Herpetologica 14:18–23).

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

HEMIDACTYLUS FRENATUS (House Gecko). HONDURAS: ISLA DE LA BAHIA: ISLA DE UTILA, town of Utila, 5 m elev. (16°6'N, 86°54'W). 18 August 2000. G. Köhler. Verified by K. Klemmer. Forschungsinstitut und Naturmuseum Senckenberg (SMF 79856). First record for Isla de Utila (Köhler 1998, Senckenbergiana Biol. 77:139–145).

Submitted by **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.M., Germany.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Bowie Co: off I-30 and U.S. Rt. 71, 1 Northgate Drive in Texarkana. 7 December 2000. James E. Welsh. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 25378). Verified by Stanley E. Trauth. Hatchling specimen (25 mm SVL) represents a new county record and the collection locale is within 300 m of the Texas/Arkansas state line. This gecko has been reported previously from 62 of 254 counties in the state, the nearest being Smith County to the southwest (Dixon 2000, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. 421 pp.).

Submitted by **CHRIS T. McALLISTER and JAMES E. WELSH**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA.

MABUYA NIGROPUNCTATA. BRAZIL: MATO GROSSO DO SUL: Brasilândia (21°15'S, 52°02'W). August 2000. F. L. Franco and R. A. K. Ribeiro. Museu Nacional, Rio de Janeiro (MNRJ 8023). Verified by D. M. Borges-Nojosa. New state record and southernmost recorded locality. Species is widely distributed throughout Amazonia, but also occurs in "cerrado" areas and was previously known from such habitats in the states of Mato Grosso and Goiás (Araújo 1994, *In* Nascimento, Bernardes, and Cotta [eds.], Herpetologia no Brasil, I. PUC-MG, Belo Horizonte: pp. 58–68; Ávila-Pires 1995, Zool. Verh. 299:1–706).

Submitted by **DAVOR VRCIBRADIC**, Setor de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier, 524, Maracanã, 20550-011, Rio de Janeiro, Rio de Janeiro, Brazil.

SCELOPORUS JARROVII (Yarrow's Spiny Lizard). USA: ARIZONA: Graham Co: E side of Galiuro Mts., Deer Creek (32°39.37'N, 110°16.86'W; 1450 m elev.). 30 August 2000. E. F. Enderson and R. L. Bezy. UAZ 52117; High Creek Trail, ca 1.6 km above trailhead. 4 June 1965. W. C. Sherbrooke. UAZ 14958-60. Both verified by P. C. Rosen. First records from the Galiuro Mts.; extends range ca 35 km W of Pinaleño (Graham) Mts.

(Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Second Ed. Houghton Mifflin, Boston, Massachusetts. ix + 336 pp.).

Submitted by **ERIK F. ENDERSON**, School of Renewable Resources, University of Arizona, Tucson, Arizona 85721, USA, **ROBERT L. SERPENTES

BOTHRIECHIS SCHLEGELII (Eyelash Palm Pit Viper). ECUADOR: PROVINCIA DE MANABÍ: Parque Nacional Machalilla: San Sebastián (ca. 1°35'S, 80°40'W), 400–900 masl. 11 October 1992. M. Garilanez. Museo Zoológico de la Pontificia Universidad Católica del Ecuador (QCAZ 1497). Verified by Luis A. Coloma. Extends known range of species 150 km SW, 100 km W, and 110 km NW from published localities in Ecuador (Kuch and Freire 1995, Herpetozoa 8:49–58). Natural vegetation at the locality is coastal cloud forest. This is the first record of *B. schlegelii* for the Machalilla National Park (Zambrano B. and Vargas A. 1998, Parque Nacional Machalilla. Quito, Imprenta Crissan Color. 92 pp.), and the highest elevation known to be inhabited by the species west of the Cordillera Occidental of the Andes in Ecuador.

Submitted by **ULRICH KUCH**, Sektion Herpetologie, Forschungsinstitut und Naturmuseum Senckenberg, Senckenberganlage 25, 60325 Frankfurt am Main, Germany.

BOTHROPS ALTERNATUS (Urutu). BRAZIL: GOIÁS: Mineiros, Emas National Park (18°20'S, 53°00'W, 760-880 m elev.). 4 April 1997. C. Nogueira. Instituto Butantan, São Paulo, Brazil (IB 57085–86). Verified by F. L. Franco. First vouchered record for the state of Goiás and for the cerrado in Central Brazil; extends range about 200 km northward (Campbell and Lamar 1989, The Venomous Reptiles of Latin America, Cornell Univ. Press, Ithaca, New York. p. 181; McDiarmid et al. 1999, Snake Species of the World, Publ. Herpetol. League. p. 253). Both snakes were found in *campo sujo* (shrubby cerrado grassland) habitat, in seasonally dry, xerophytic interfluvial savannas.

Submitted by **CRISTIANO NOGUEIRA**, Laboratório de Ecologia e Evolução de Vertebrados, Departamento de Ecologia, Universidade de São Paulo, Caixa Postal 11461, CEP 05422-970, São Paulo, São Paulo, Brazil (e-mail: crinog@ib.usp.br), and **PAULA H. VALDUJO**, Laboratório de Herpetologia, Instituto Butantan. Avenida Vital Brasil, 1500, CEP 05503–900, São Paulo, São Paulo, Brazil.

CHIRONIUS SCURRULUS (Machete). VENEZUELA: ESTADO AMAZONAS: Ocamo, Río Ocamo. 153 m elev. 29 March 1972. R. Hoogesteijn. Museo de Historia Natural La Salle, Caracas (MHNLS 5698). Juvenile, 335 mm SVL. Lancini (1979, Serpientes de Venezuela. Armitano Ed. 262 pp.) had previously reported a specimen collected in San Carlos de Río Negro, Amazonas, without museum data. The specimen reported herein constitutes the first documented voucher for the state of Amazonas and the southernmost locality in Venezuela. Extends known distribution at least 325 km E of previous locality in Río Paragua (Hoge 1969, Mem. Inst. Butantan 34:85; Lancini and Kornacker 1989, Die Schlangen von Venezuela. Verlag Armitano Editores. 381 pp.). The discovery, on the same day and in the same place, of a juvenile of *C. exoletus* (MHNLS 5700) and an adult of *C. fuscus* (MHNLS 5890), demonstrates sympatry of the three species of this genus. ESTADO BOLIVAR: La Escalera, ca. 800 m elev. 25 May 1989. José Ayarzagüena. Museo de Historia Natural La Salle (MHNLS 11341). Adult male, 1020 mm SVL. All verified by Cesar Molina. Although Hoge (*op. cit.*) first reported the species from Venezuela, based on an uncataloged specimen deposited in the Museo de Biología de la Universidad Central de Venezuela, Caracas, and purported to come from the state of Bolívar, the specimen reported herein is the first documented record for the state. The only other documented records of this taxon in Venezuela are those of Dixon et al. (1993, Mus. Reg. Sci. Nat. Torino. Monog. XIII. 279 pp.) for the state of Monagas, and Rivas and Oliveros (1997, Mem. Soc. Cienc. Nat. La Salle 147: 67–80) for the state of Sucre. These records demonstrated that the snake has a more extensive distribution in Venezuela, but is limited to the Venezuelan Guayana, the latter understood as encompassing the states of Amazonas, Bolívar, Delta Amacuro, eastern Monagas and southeastern Sucre, as defined by Gorzula and Señaris (1998, Contribution to the Herpetofauna of the Venezuelan Guayana I. A data base. Scientia Guaianae 8, 270 pp. + 32 color plates).

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Sección de Herpetología, Apartado Postal 1930, Caracas 1010-A, Venezuela (e-mail: gilsonrivas@mixmail.com) and **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales y Ambientales, Laboratorio de Biogeografía, Colección de Anfibios y Reptiles, Mérida 5101, Venezuela (e-mail: lamarca57@cantv.net).

CLELIA CLELIA (Mussurana). VENEZUELA: ESTADO AMAZONAS: Cunucunuma River, 8 km SW of Acanaña (03°09'82"N, 66°02'82"W). 170 m elev. 15 April 1990. Wilmer Villalobos. Museo de Historia Natural La Salle, Caracas (MHNLS 11761). Adult male, 1420 mm SVL. First state record and southernmost record in Venezuela. ESTADO MERIDA: Caserío la Florida, W of Poblado las Virtudes (09°08'82"N, 70°52'82"W), 950–970 m elev. 28 December 1977. Alfredo Paolillo. MHNLS 7146. Adult male, 1350 mm SVL. First state record and the westernmost locality in Venezuela. First specimen from the Andean Cordillera de Mérida. ESTADO APURE: Hato el Frío, La Apontera (07°44'28"N, 69°02'20"W). 70 m elev. February 1990. José González. MHNLS 11586. Adult male, 1245 mm SVL. First state record and first documented voucher from the Venezuelan Llanos region (Rivero-Blanco and Dixon 1979, *In* Duellman [ed.], Mus. Nat. Hist. Univ. Kansas Monog. 7:281–98). All verified by César Molina. Species had been reported for some localities in the Venezuelan states of Aragua, Bolívar, Carabobo, Guarico, Miranda, Sucre, and Distrito Federal (Zaher 1996, Boll. Mus. reg. Sci. nat. Torino 14[2]:289–337; Roze 1966, La Taxonomía y Zoogeografía de los Ofidios en Venezuela. UCV, Edic. Bibli. 362 pp.; Rivas and Oliveros 1997, Mem. Soc. Cienc. Nat. La Salle 147:67–80). These new records suggest that this taxon has a wider distribution in Venezuela than was previously known.

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Sección de Herpetología, Apartado Postal 1930, Caracas 1010-A, Venezuela (e-mail: gilsonrivas@mixmail.com) and **ENRIQUE LA MARCA**, Universidad de Los Andes, Facultad de Ciencias Forestales y Ambientales, Laboratorio de Biogeografía, Colección de Anfibios y Reptiles, Mérida 5101, Venezuela (e-mail: lamarca57@cantv.net).

COLUBER FLORULENTUS FLORULENTUS (Flowered Racer). EGYPT: NORTH SINAI: Al-Arish City, (31°07'55"N, 32°45'20"E). 25 October 1999. Adel A. Ibrahim. Muséum National d'Histoire Naturelle, Paris (MNHN 1999.9453). Verified by Ivan INEICH. A juvenile (246 mm SVL) captured from a house in Fawakhreya, one of the oldest districts of the town. Snake was probably introduced from the Nile Delta, and more than likely from the Sharqia Province via cattle fodder and clover vehicles. In Egypt, this species has been recorded from the Nile Valley and Delta, Faiyum and Wadi El Natrun (Saleh 1997, Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. XI, 234 pp.). First record for the Sinai Peninsula (Werner 1982, *In* N. J. Scott, Jr. [ed.], Herpetological Communities, pp. 153–161. U.S. Fish and Wildlife Service Wildl. Res. Rep. 13).

Submitted by **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt (e-mail: aibrahim@ismailia.ie-eg.com).

DIADOPHIS PUNCTATUS STICTOGENYS (Mississippi Ringneck Snake). USA: ARKANSAS: Phillips Co: SE 1/4 Sec. 7, R5E, T1S, ca. 100 m N jct. of Phillips County Roads 239 and 211, St. Francis National Forest. 11 November 2000. L. K. Irwin and K. J. Irwin. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 25370). Verified by Stanley E. Trauth. Adult female found under ca. 250 mm diameter log in bed of dried cypress-tupelo gum slough in bottomland hardwood forest adjacent to base of eastern versant of Crowley's Ridge. An adult female Marbled Salamander (*Ambystoma opacum*) with egg clutch was under same log, ca.1.3 m spatial distance between individuals. First record for county and second record east of White River basin in Mississippi River floodplain of Arkansas (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **LISA K. IRWIN**, 355 Granddaddy Lane, Mabelvale, Arkansas 72103, USA, and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA.

DRYMOBIUS RHOMBIFER. BRAZIL: AMAZONAS: Benjamin Constant: Itacuari River between Pedras and Ituhry rivers (04°22'59"S, 70°01'52"W). May 1942. C. Parko. Museu Nacional, Brazil (MNRJ 1549). Verified by Ronaldo Fernandes. Male specimen; third record for Brazil and new state record. Previously known in Brazil from Isle of Maracá, state of Roraima (O'Shea 1998, *In* Maracá: The Biodiversity and Environment of an Amazon Rainforest, pp. 231–262. John Wiley and Sons) and from the state of Rondônia (Vanzolini 1986, Levantamento herpetológico da área do estado de Rondônia sob a influência da rodovia BR 364, Conselho Nacional de Pesquisas, Brasíla, DF. 50 pp).

Submitted by **PAULO PASSOS**, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista s/n, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

GYALOPION CANUM (Western Hooknose Snake). MÉXICO: JALISCO: Atotonilco el Alto, municipality of Atotonilco el Alto, 1550–1600 m (20°34'N, 102°31'W). August 2000. Raymundo López-Azpeitia. Universidad Autónoma de Guadalajara, México (UAGM-R-426). Verified by H. M. Smith. Range extension; nearest previously known records were from 145 km SW at Tapalpa, Jalisco (Ponce and Huerta, in prep.) and 191 km W and 3 km S Carapán, Michoacán (Ponce and Huerta 1999, Herpetol. Rev. 30:113).

Submitted by **PAULINO PONCE-CAMPOS**, **SARA M. HUERTA-ORTEGA**, and **HECTOR DE LA MORA-NAVARRO**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

HETERODON NASICUS (Western Hognose Snake). **CORRECTION**. USA: ARKANSAS: Polk Co: Skyline Drive on top of Rich Mountain at western boundary of Queen Wilhelmina State Park. 27 June 1975. D. B. Means, J. B. Atkinson, and G. H. Means. UF/FSM 34807. Means (1976, Herpetol. Rev. 7:123) originally recorded this specimen as the first Arkansas record for *Heterodon nasicus*, extending the range 391.5 km from western

Oklahoma or northeastern Texas. Recent examination of the specimen confirms that it is actually a subadult *Heterodon platirhinos,* thus eliminating this species from the herpetofauna of Arkansas. Verified by Joseph T. Collins and Stanley E. Trauth.

Submitted by **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA.

HYDROPS TRIANGULARIS (Triangle Water Snake) BRAZIL: MATO GROSSO: Teles Pires River (07°21'S, 58°03'W). Date and collector unknown. Herpetological Collection of the Instituto Butantan, São Paulo, Brazil (IB 30868). Young male. Several works have listed the snake fauna of the state of Mato Grosso (Amaral 1925, Comissão de linhas telegrafhicas estratégicas de Mato Grosso ao Amazonas; Nascimento et al. 1988, Bol. Mus. Para. Emílio Goeldi, sér. Zool. 4[1]:21–66; Strussmann and Carvalho 1998, Herpetol. Rev. 29:183–185; Strussmann and Sazima 1993, Studies on Neotropical Fauna and Environment 28[3]:157–168) and, until now, none of them had recorded *Hydrops triangularis* for this region. First state record. MATO GROSSO DO SUL: Aquidauana Municipality (20°28'S, 55°48'W). An adult specimen. IB 29171. According to the only list on the snake fauna of the state of Mato Grosso do Sul (Koslowsky 1898, Rev. Mus. La Plata pp. 25–33), this is the first state record. Both verified by Thales De Lema.

Submitted by **NELSON RUFINO DE ALBUQUERQUE**, Linha de Pesquisa em Herpetologia, Pontifícia Universidade Católica do Rio Grande do Sul, Avenida Ipiranga 6681, CEP: 90619-900, Porto Alegre- Rio Grande do Sul, Brazil.

HYPSIGLENA TORQUATA JANI (Texas Night Snake). USA: TEXAS: Mason Co: Mason County Wildlife Management Area (30°49.204'N, 79°13.422'W). 25 March 2000. Joel McKinney, David Etheredge, and students in an Introductory Wildlife Class collected one specimen from under a prickly pear cactus (*Opuntia*) along the base of a large granite boulder. TCWC 83982. Verified by James. R. Dixon. New county record (Dixon 1997, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station).

Submitted by **JOEL McKINNEY** and **DAVID ETHEREDGE**, Biology Department, South Plains College, Levelland, Texas 79336, USA (e-mail: jmckinne@spc.cc. tx.us).

LIOCHLOROPHIS VERNALIS (Smooth Green Snake). USA: COLORADO: Pueblo Co: the town of Rye, near Rye Elementary School, Sec. 30, T24S, R67W. 5 October 2000. Margaret DiMatteo and Paul J. Hurtado. UCM Ancillary Collection of Herpetological Slides and Prints 148–149. Verified by Hobart M. Smith. First county record (Hammerson 1999, Amphibians and Reptiles of Colorado. Second Ed. Univ. Colorado Press, Niwot. xxviii + 484 pp.).

Submitted by **CHARLES W. LOEFFLER**, Colorado Department of Natural Resources, Division of Wildlife, 6060 Broadway, Denver, Colorado 80216, USA.

LIOPHIS ATRAVENTER. BRAZIL: RIO DE JANEIRO: Teresópolis (22°24'S, 42°57'W). L. Davies. 17 March 1943. Museu Nacional, Brazil (MNRJ 2766). Verified by R. Fernandes. An adult female. Species was originally described by Dixon and Thomas (1985, Herpetologica 41:259–262) based on three specimens from the Biological Station Boracéia, state of São Paulo, Brazil (23°38'S, 45°52'W). The record reported herein represents a new state record and is the fourth known specimen of thes species; extends distribution about 235 kilometers from the type locality.

Submitted by **PAULO PASSOS** and **DANIEL S. FERNANDES**, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista s/n, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil (e-mail: danfer@acd.ufrj.br).

LIOPHIS BREVICEPS BREVICEPS. BRAZIL: PARÁ: Itaituba (4°17'S, 55°59'W) on left bank of the Tapajós River. 1996. R. L. M. de Oliveira. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1339). Verified by Rubens N. Yuki. The taxon is known from forested parts of the Amazon Basin in Bolivia, Brazil, Colombia, Perú, and similar areas in French Guiana, Guyana, Suriname, and Venezuela. Represents the first record for the western portion of the state of Pará and fills the distributional gap between previously known localities. Specimen was collected 234 km airline from Santarém, the nearest previous record (Dixon 1983, J. Herpetol. 17:149–165).

Submitted by **JOSSEHAN GALÚCIO DA FROTA**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200 (e-mail: jgfrota@mailbr.com.br).

MICRURUS CORALLINUS (Painted Coral Snake). BRAZIL: RIO GRANDE DO NORTE: Natal, Parque Estadual das Dunas (05°47'–5°56'S and 35°10'–35°11'W). 27 April 2000. B. R. A. França. Coleção do Departamento de Botânica, Ecologia e Zoologia, Universidade Federal do Rio Grande do Norte (CDBEZ 407). Verified by Ulisses Caramaschi and Ronaldo Fernandes. In leaf litter of forest among coastal dunes. First record for the state; this specimen extends distribution ca. 1400 km N Minas Gerais and Espírito Santo, Brazil (Roze 1996, Coral Snakes of the Americas. Krieger Publ., Malabar, Florida. p. 150) and ca. 1300 km N Porto Seguro, Bahia, Brazil (Franco et al. 1998, Répteis na Estação Veracruz [Porto Seguro, Bahia]. Veracel, Publ. Técnico-Científica, n. 3, 39 pp.).

Submitted by **ELIZA MARIA XAVIER FREIRE**, Departamento de Zoologia y Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade, 452, Farol, Maceió, Alagoas, 57021-090, Brazil and Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

MICRURUS LEMNISCATUS (South American Coral Snake). BRAZIL: RIO GRANDE DO SUL: municipality of Eugênio de Castro (28°31'S, 54°08'W). 9 April 2000. E. Contry and L. H. Cappellari. Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP 11935). Verified by Nelson Jorge da Silva, Jr. First state record; southernmost record for the species, extending known range 395 km SW from União da Vitória, Paraná, Brazil, and 150 km SE from Puerto Azara, Misiones, Argentina (Jorge da Silva and Sites 1999, Herpetol. Monogr. 13:142–194).

Submitted by **MARCOS DI-BERNARDO**, **MÁRCIO BORGES-MARTINS**, and **LIZE HELENA CAPPELLARI**,

NATRIX NATRIX (Grass Snake). SPAIN: ALMERÍA: River Adra between Majaroba and Potriles (36°47'52"N, 3°00'36"W), 90 masl and 7200 m from the river's mouth. 4 September 2000. Mariano Paracuellos. Consejería de Medio Ambiente, Junta de Andalucía, Almería, Spain, Color Slides 10101–102. Verified by Jesús Mellado. First record for Almería Province (southeastern Spain). Extends range about 50 airline km E from River Guadalfeo, Granada (Santos et al. 1997, *In* Pleguezuelos [ed.], Distribución y Biogeografía de los Anfibios y Reptiles en España y Portugal, pp. 282–284. Universidad de Granada-AHE, Granada; Braña 1998, *In* Salvador [coord.], Reptiles, Fauna Ibérica, Vol. 10, pp. 454–466. Museo Nacional de Ciencias Naturales, CSIC, Madrid). Rarity of this snake in the majority of southeastern Iberia is usually ascribed to the environmental aridity there (Pleguezuelos 1989, Doñana, Acta Vertebrata 16:15–44; Santos et al., *op. cit.*; Braña, *op. cit.*), and Sierra Nevada has been considered to represent the southeastern limit of the range of this species in Spain (Pleguezuelos, *op. cit.*). Though surrounded by semi-arid environments, the fluvial bed where the present specimen was found has superficial water of good quality all year round, giving rise to a diverse composition of aquatic flora and fauna, and a dense vegetation predominated by *Arundo donax* on its banks. Such an environmental condition seems to have enabled the snake to exist in this region.

Submitted by **MARIANO PARACUELLOS**, Consejería de Medio Ambiente, Junta de Andalucía, C. R. Oliveros, bl. Singular, Almería E-04071, Spain; e-mail: paracuellos@larural.es.

OXYRHOPUS CLATHRATUS. BRAZIL: BAHIA: Barra do Choça, Recanto da Adriana farm (14°57'S, 40°33'W). March 1999. J. O. Ruas. Coleção Zoológica Gregório Bondar of the Centro de Pesquisas do Cacau/CEPLAC (CZGB 8876); 14 October–13 November 1999. J. O. Ruas. CZGB 9378. Both verified by Joaquim Cavalheiro. Previously known in southeastern Brazil from southern Minas Gerais to Rio Grande do Sul and Misiones in northeastern Argentina (Peters and Orejas-Miranda 1970, Bull. U.S. Nat. Mus. 297:231). First record from the state of Bahia and northeastern Brazil.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO** Universidade Estadual de Santa Cruz—UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil; e-mail: ajargolo@hotmail.com.

SALVADORA HEXALEPIS (Western Patchnose Snake). USA: CALIFORNIA: Kern Co: Lokern Natural Area, Sec. 29, T29S, R22E. 7 August 2000. Kathy Sharum and Rochelle Germano. LACM Color Slides PC 1340–41. Verified by R. W. Hansen. Specimen represents only the second record for the western portion of the southern San Joaquin Valley, and was found less than 2 km from the previous record (Cameron and Hansen 1994, Herpetol. Rev. 25:34–35). The locality is between the known ranges of the subspecies *S. h. virgultea*, known to occur on the Carrizo Plain to the west, and *S. h. mojavensis*, found ca. 60 km to the E in Bakersfield (Bogert 1945, Amer. Mus. Novitates 1285:1–14; Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts. 336 pp.; Cameron and Hansen 1994, *op. cit.*). Unlike the first record, this specimen was kept and thoroughly examined. Its characters are mostly those of *mojavensis:* undivided loreal scale, no upper labial scales reaching the eye, and the vertebral stripe is three scale rows wide (Bogert 1945, *op. cit.*). However, the sides are more uniformly gray than is typical for *mojavensis*, and thus are similar to *virgultea*.

Submitted by **DAVID J. GERMANO**, Department of Biology, California State University, Bakersfield, California 93311-1099, USA; e-mail: dgermano@csubak.edu.

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: Arkansas: Arkansas Co: Sec. 14, T7S, R2W, White River National Wildlife Refuge. 10 October 2000. K. J. Irwin and W. B. Blihovde. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 25343). Verified by Stan Trauth. Adult male found under log in second growth bottomland hardwood forest. First record for county, the third and most easterly record for the species in the Mississippi River floodplain of Arkansas (Trauth, Robison, and Plummer, *in prep.*).

Submitted by **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA, and **W. BOYD BLIHOVDE**, White River National Wildlife Refuge, P.O. Box 308, DeWitt, Arkansas 72042, USA.

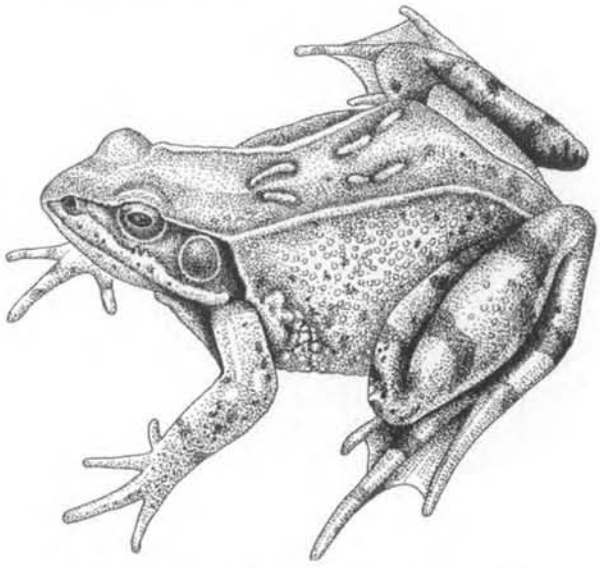
SISTRURUS MILIARIUS (Pigmy Rattlesnake). USA: Arkansas: Arkansas Co: NE 1/4, Sec. 25, R2W, T7S, ca. 1.5 km W of jct. Co. Rt. 44 and Lagrue Bayou. 20 September 2000. Paul Gideon. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 25344). Verified by Stan Trauth. Adult found DOR. First record for county, fourth record for the species in the Mississippi River floodplain of Arkansas (Trauth, Robison, and Plummer, *in prep.*).

Submitted by **W. BOYD BLIHOVDE**, White River National Wildlife Refuge, P.O. Box 308, DeWitt, Arkansas 72042, USA, and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA.

STORERIA OCCIPITOMACULATA OBSCURA (Florida Redbelly Snake). USA: FLORIDA: St. Johns Co: Guana River Wildlife Management Area (30°06'17"N, 81°21'12"W). 26 March 2000. Scott Krueger. UF 121360. Verified by F. Wayne King. New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second Ed. Windward Publ., Miami, Florida. 176 pp.). Collected in xeric oak scrub habitat.

Submitted by **JOSIAH H. TOWNSEND** and **KENNETH L. KRYSKO**, Florida Museum of Natural History, Division of Herpetology, Gainesville, Florida 32611, USA, and **SCOTT A. KRUEGER**, 2801 Green Acres Road Extension, St. Augustine, Florida 32084, USA.

TYPHLOPS DEPRESSICEPS (Beaked Blind Snake). PAPUA NEW GUINEA: WEST NEW BRITAIN PROVINCE: Willaumez Peninsula, ca. 17 km S of Talasea and 3 km W of Walindi Plantation,



(5°26.04'S, 150°3.46'E) ca. 150 masl. 13 April 1999. Johannes Foufopoulos. University of Wisconsin Museum of Zoology (UWMZ H.23647). Verified by A. Wynn and V. Wallach. First record for the island of New Britain. This lowland species is currently known only from a handful of specimens collected primarily along the north coast of Papua New Guinea and offshore Kiriwina Island. Specimen was found under a rotten log in the immediate vicinity of the Walindi River in mature primary rainforest. The specimen is an immature individual with the following data: 780 middorsals, 29 subcaudals, 22-22-20 scale rows, SVL 220 mm, TL 229 mm, fresh mass weight 1.55 g.

Submitted by **JOHANNES FOUFOPOULOS**, Department of Ecology and Evolutionary Biology, Guyot Hall, Princeton University, Princeton, New Jersey 08544-1003, USA (e-mail: jfoufop@princeton.edu).

Correction

In reviewing literature pertaining to distributions of Georgia herpetofauna, I discovered an error that I wish to correct. Laerm et al. (1996. Herpetol. Rev. 27:91–92) reported three species of amphibians and one reptile that represented new records for Dade County, Georgia. All localities are within the Crocford-Pigeon Mountain Wildlife Management Area, which lies entirely within Walker County. Of the species listed by Laerm et al. (1996, *op. cit.*), *Gastrophryne carolinensis* (Eastern Narrowmouth Toad), *Scaphiopus holbrookii holbrookii* (Eastern Spadefoot Toad), and *Virginia valeriae valeriae* (Eastern Smooth Earth Snake) are county records for Walker County (Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. Savannah Sci. Mus. Spec. Pub. 3:1–712); however, *Ambystoma talpoideum* (Mole Salamander) was previously reported from Walker County (Jensen 1996. Herpetol. Rev. 27:28).

Field work at two localities in La Reserva de la Biósfera Río Plátano, deptos. Colón and Olancho, Honduras, in 1998 and 1999 resulted in the collection of three species of snakes not previously known to occur in Honduras. The species are discussed below, including their color in life, following the colors and codes of Smithe (1975–1981). Museum abbreviations follow those of Leviton et al. (1985).

Ninia maculata (Peters). A single adult female (USNM 535992; SVL of 186 mm and a total length of 245 mm) was collected at 540 m elevation under a small log at Quebrada Machín, Depto. Colón, on 3 August 1999. The specimen has narrow crossbands on the body (closest to Fig. 2B in Savage and Lahanas 1991), a broad nuchal collar (most similar to Fig. 3B in Savage and Lahanas 1991, although the collar is not divided down the midline), and a strongly checkered venter (pattern most similar to Fig. 4H in Savage and Lahanas 1991). Scalation characters of USNM 535992 are typical of *N. maculata*, as defined by Savage and Lahanas (1991). The overall color pattern and segmental counts (127 ventrals, 52 subcaudals, 179 ventrals plus subcaudals) agree with the Atlantic Lowlands population of *N. maculata*, as defined by Savage and Lahanas (1991). The Honduran specimen represents a range extension of about 160 airline km NNW of the Big Falls, Zelaya (= Depto. Atlántico Norte), Nicaragua, locality in Savage and Lahanas (1991). Color in life of USNM 535992: dorsum of body Burnt Umber (22), with Blackish Neutral Gray (82) dorsal crossbands; dorsum of head Dark Grayish Brown (20); supralabials with pale cream and very dark brown markings; venter pale cream with Dusky Brown (19) checkering; iris gray with darker flecking.

Sibon longifrenis (Stejneger). Six specimens (three males [USNM 535994, 535996, 535998] and three females [USNM 535993, 535995, 535997]) were collected between 540 and 700 m elevation on vegetation 2–3 m above streams at Quebrada de Las Marías, Depto. Olancho (five specimens), and Quebrada Machín, Depto. Colón (one specimen). All specimens were active at night on 1–2 August 1998 and 1 August 1999. Comparison of these specimens to the data provided by Savage and McDiarmid (1992) revealed that they agree with their definition of *S. longifrenis* in most de-

tails. However, the Honduran material differs in ventral pattern from the illustration and description of *S. longifrenis* provided by Savage and McDiarmid (1992) by lacking significant stippling on these surfaces. In fact, the ventral pattern of the Honduran specimens most closely resembles that of *S. argus*, as illustrated (their Fig. 2B) and described by Savage and McDiarmid (1992). Thus, the Honduran material was compared directly to the holotype of *Mesopeltis longifrenis* Stejneger (USNM 38750) from Panama and five specimens from Costa Rica identified as *S. longifrenis* by Savage and McDiarmid (CRE 6701; KU 25703; UF 31787, 77732; UMMZ 117502), as well as the holotype of *Leptognathus argus* Cope (USNM 30656) from Costa Rica and three specimens from Panama identified as *S. argus* by Savage and McDiarmid (KU 75752–53, 112473). *Sibon longifrenis* and *S. argus* differ significantly from each other in head shape, eye size, number of ventrals, and number of subcaudals. The Honduran specimens agree with the specimens we examined of *S. longifrenis* in these significant characters. However, the differences in ventral pattern between the Honduran material and that of *S. longifrenis* from Costa Rica and Panama remain obvious in direct comparison, except that one Costa Rican *S. longifrenis* (UF 77732) has less ventral stippling than the remaining *S. longifrenis*, and approximates the pattern seen in the Honduran material. Thus, we consider the Honduran specimens to be conspecific with *S. longifrenis* from Costa Rica and Panama. The Honduran specimens represent a range extension of about 530 airline km NNW of the Heredia, Costa Rica, localities reported by Savage and McDiarmid (1992).

Savage and McDiarmid (1992) had only nine specimens of *Sibon longifrenis* available for their analysis. Thus, we provide the following pertinent data for the six Honduran specimens: enlarged penultimate supralabial bordering orbit; loreal bordering orbit on 9 of 12 sides, one large preocular present on 3 of 12 sides, 1 small preocular present below loreal on 6 of 9 remaining sides; 1–3 (usually 2) postoculars; 7–7 supralabials (fourth, fifth, and sixth bordering orbit), sixth supralabial enlarged in all; infralabials 6–8, none in contact behind mental; 1+2 (2+3 on one side) temporals; 0–1 postmentals (usually 1 very small postmental present); dorsal scales in 15–15–15 smooth rows, vertebral row not enlarged; ventrals 166–169 (167.3, N = 3) in males, 159–165 (161.7, N = 3) in females; subcaudals 106 in both males with complete tails, 91–98 (95.7, N = 3) in females; total segmental counts 272–275 (273.5, N = 2) in males, 250–263 (257.3, N = 3) in females. The color pattern of the Honduran material agrees well with that provided for *S. longifrenis* by Savage and McDiarmid (1992), except that the ventral surfaces are cream (in preservative) with longitudinal dark brown mottling, mottling not confined to lateral edges of ventrals and not forming a zig-zag pattern. There are 27–41 (34.5) single dorsal ocelli and 0–12 (5.8) paired ocelli. The largest male (USNM 535998) has a SVL of 389 mm and a total length of 577 mm; the largest female (USNM 535997) has a SVL of 368 mm and a total length of 541 mm. Color in life of USNM 535993: dorsum of body Bunting Green (150), with black outlined Ferruginous (41) ocelli crossbands, some of which are broken into dorsal and lateral portions, these crossbands separated laterally by ivory blotches; dorsum of head Bunting Green (150), with black outlined Ferruginous (41) blotches; venter Spectrum Yellow (55) with black longitudinal mottling, mottling streaked with Ferruginous (41); iris pale olive green, with black and rust-red speckling.

Urotheca guentheri (Dunn). Two adult males (USNM 535999–6000; SVL 265 mm and total length 465 mm and SVL 215 mm and tail incomplete, respectively) were collected at 540 m elevation less than 1 m apart inside the same rotten log at Quebrada Machín, Depto. Colón, on 4 August 1999. Both specimens agree well with the description of this species by Myers (1974, as *Rhadinaea*). Both specimens have 140 ventrals and the specimen with the complete tail has 109 subcaudals. USNM 535999 is nearly 30 mm longer than the longest male available to Myers (1974). The Honduran specimens represent a range extension of about 170 airline km NNW of the Eden Mine, Zelaya (= Depto. Atlántico Norte), Nicaragua, locality in Myers (1974). Color in life of USNM 535999: dorsum of body Warm Sepia (221A) between dorsolateral pale stripes, with median row and portions of paravertebral rows with an olive tint; paired dorsolateral stripes Cinnamon (39); lateral field (between dorsolateral and lateral pale stripes) Walnut Brown (221B), heavily flecked with Sepia (219); paired lateral stripes Drab-Gray (119D); lower half of scale row 1 and lateral edge of ventrals Sepia (119); dorsum of head Warm Sepia (221A); pale spot posterior to eye Cream Color (54); spots just posterior to head Cinnamon (39); lower portion of supralabials pale cream, Burnt Orange (116) along lip line on supralabials 4–6; venter Burnt Orange (116); iris rust-red. Savage and Crother (1989) placed the members of Myers' (1974) *Rhadinaea lateristriga* group (to which *R. guentheri* belongs) in the genus *Urotheca* Bibron. Myers and Cadle (1994) concurred with this placement.

Acknowledgments.—The following colleagues provided comparative material of *Sibon*: K. Beaman and D. Kizerian (CRE material, now housed at LACM); A. Resetar (FMNH); H. Alamillo and J. E. Simmons (KU); J. Hanken and J. Rosado (MCZ); S. Feliciano (UF); A. G. Kluge and G. Schneider (UMMZ); and R. W. McDiarmid (USNM). Field assistance was provided by J. H. Townsend and K. L. Williams. Collecting and export permits were issued by A. Barahona and C. Romero of COHDEFOR, Tegucigalpa. Valuable assistance with securing these permits was provided by M. R. Espinal.

e-mail: john_jensen@dnr.state.ga.us

The following specimens from the Louisiana State University Museum of Natural History (LSUMZ) represent new Georgia county records (Jensen and Moulis 1997, 1999; Williamson and Moulis 1994). All specimens were verified by Jeff Boundy.

Ambystoma opacum (Marbled Salamander). BARTOW CO: Cartersville. August 1967. C. Wilson. LSUMZ 52189.

Desmognathus monticola (Seal Salamander). CHATTOOGA CO: Unnamed creek feeding lake in James H. "Sloppy" Floyd State Park. 4 June 1993. J. Carlin and D. O'Quinn. LSUMZ 56070.

Plethodon chlorobryonis (Atlantic Coast Slimy Salamander). BANKS CO: 6.5 km E of Baldwin near White House Creek. 15 November 1997. C. Camp. LSUMZ 59688.

Plethodon jordani (Jordan's Salamander). TOWNS CO: Tate Branch Recreational Area. 5 May 1973. G. Hardaway and T. Hardaway. LSUMZ 62532.

Plethodon serratus (Southern Redback Salamander). FLOYD CO: John's Creek at The Pocket, Chattahoochee National Forest. 19 May 1994. J. Carlin. LSUMZ 56600.

Pseudotriton montanus montanus (Eastern Mud Salamander). ROCKDALE CO: Rest Area on I-20, 1.6 km E jct. U.S. Rt. 138. 11 April 1971. D. Marshall. LSUMZ 23975.

Cnemidophorus sexlineatus sexlineatus (Sixed-lined Racerunner). STEWART CO: 4.4 km N of Lumpkin. 18 May 1963. D. Drapalik. LSUMZ 54520. Removed from the stomach of a *Masticophis flagellum* (LSUMZ 6710) collected from the stated locality.

Cemophora coccinea (Scarlet Snake). MUSCOGEE CO: Fort Benning Military Reservation. 7 August 1971. P. Strong. LSUMZ 75950.

Crotalus horridus (Timber Rattlesnake). COBB CO: Vicinity of Marietta. September 1965. H. Morris. LSUMZ 38644.

Elaphe guttata (Corn Snake). BARTOW CO: 6.5 km E of Cartersville. 27 June 1967. C. Wilson. LSUMZ 30017.

Regina septemvittata (Queen Snake). GORDON CO: Pumpkin Vine Creek at US Rt. 41. May 1959. S. Lee. LSUMZ 8848.

and

DANIEL ROBERTO PEREZ
ISFPD-Villa Regina, San Luis 327, 8336, Villa Regina, Río Negro, Argentina

Field work in southern Argentina during the austral summer of 2000 and a review of herpetological material deposited in another collection has resulted in new records for six species of lizards and two species of snakes. Gustavo Scrocchi verified the identification of all specimens. All specimens have been deposited at Fundación Miguel Lillo (FML), San Miguel de Tucumán, Tucumán, Argentina. Latitude and longitude were determined with a Garmin GPS 38 global positioning device for the species collected by the first two authors and geographic coordinates for localities of specimens collected by DRP were determined with the Atlas de la República Argentina, I-Parte Política, Instituto Geográfico Militar (1972).

Polychrotidae

Diplolaemus darwini. CHUBUT PROVINCE: Departamento Florentino Ameghino: on Ruta Provincial Número 30, 37 km W Camarones (44°42'05"S, 66°08'54"W). 20 January 2000. L. J. Avila and M. Morando. FML 9143.

First province record and northeasternmost known locality for the species. This record extends the range reported for this species by Cei (1986) ca. 200 km NE (airline). Habitat was shrub-grass steppe. According Cei (1986), the populations north of Santa Cruz-Chubut boundaries are difficult to identify. But this specimen is clearly an individual of *Diplolaemus darwini*, so it is the first documented record for the species in this province.

Pristidactylus fasciatus. RIO NEGRO PROVINCE: Departamento General Roca: 35 km NE Chichinales (38°49'00"S, 66°47'00"W). January 1997. D. R. Perez. FML 9319.

First specific locality record south of La Pampa Province except for the type locality; confirms unvouchered citation for Rio Negro Province (Etheridge and Williams 1985; Koslowsky 1898). Specimen was collected using a pitfall trap made in a depression of sandy substrate. Other species observed at this site were *Liolaemus darwinii*, *Liolaemus gracilis*, *Homonota fasciata*, and *Homonota* cf. *darwinii*.

Tropiduridae

Phymaturus patagonica. RIO NEGRO PROVINCE: Departamento Ñorquinco: on rock boulders along the roadside of Ruta Provincial Número 6, 1 km NW Ojo de Agua (41°32'30"S, 69°51'33"W). 28 January 2000. L. J. Avila and M. Morando. FML 9320–21.

Second record for the province and first record for Departamento

Ñorquinco (Avila et al. 1999). Westernmost locality and extends the range of the species ca. 150 km SW in Rio Negro and more than 300 km for any previously known locality in Chubut province. Specimens of this population exhibit a remarkable chromatic variation, unlike that of other *Phymaturus patagonica*. *Liolaemus* cf *petrophilus*, *Liolaemus rothi*, *Liolaemus bibroni*, *Liolaemus kriegi*, and *Homonota darwinii* were also found at this locality.

Liolaemus cuyanus. LA PAMPA PROVINCE: Departamento Puelen: 7 km NE Casa de Piedra (38°07'26"S, 67°06'19"W). 29 January 2000. M. Morando and L. J. Avila. FML 9146.

Second record for La Pampa Province; constitutes a range extension of ca. 60 km south from previous record (Cruz et al. 1999). Specimens of this population exhibit a remarkable chromatic variation, unlike that from northern populations. Subtrate was loose sand covered with medium-sized bushes, but lacking dunes or extensive open areas. *Liolaemus darwini*, *Liolaemus* cf. *melanops*, *Liolaemus gracilis* and *Cnemidophorus longicaudus* were also found at this locality.

Liolaemus kriegi. RIO NEGRO PROVINCE: Departamento Ñorquinco: on rock boulders along the roadside of Ruta Provincial Número 6, 1 km NW Ojo de Agua (41°32'30"S, 69°51'33"W). 28 January 2000. L. J. Avila and M. Morando. FML 9322.

This species was collected at the same locality as *Phymaturus patagonica* and confirms the presence of *L. kriegi* in western Rio Negro province, considered uncertain by Cruz et al. (1999).

Liolaemus petrophilus. CHUBUT PROVINCE: Departamento Paso de Indios: Valle de los Mártires, on rock boulders along the roadside of Ruta Nacional Número 25, 19 km E jct. Ruta Provincial Número 27 (43°49'41"S, 67°45'21"W). 24 January 2000. M. Morando and L. J. Avila. FML 9323.

Southwesternmost locality; extends the range of this species at least 100 km from any previously known locality in Chubut province (Cei 1986; Scolaro 1993). The range of this species may extend to the southern boundaries of Chubut province, based on our observations in the San Bernardo Mountains.

Colubridae

Phalotris bilineatus. CHUBUT PROVINCE: Departamento Rawson: on Ruta Nacional Número 3, 17 km N Trelew (43°05'52"S, 65°14'17"W). 16 January 2000. M. Morando and L. J. Avila. FML 9324. Southernmost record for the species (Scolaro and Cei 1979) and first departamental record. RIO NEGRO PROVINCE: Departamento El Cuy: Valle Azul, 15 km SE Chichinales (39°07'00"S, 66°56'00"W). January 2000. D. R. Perez. FML 9382. Second vouchered record for Rio Negro Province; extends range reported for the species ca. 150 km to southwest. Closest records are in La Pampa Province and eastern Rio Negro province (Vega and Bellagamba 1994).

Philodryas patagoniensis. RIO NEGRO PROVINCE: Departamento 25 de Mayo; on Ruta Provincial Número 6, 11 km S Ingeniero Jacobacci (41°20'40"S, 69°41'30"W). 28 January 2000. L. J. Avila and M. Morando. FML 9144.

A range extension of ca. 200 km south from the ca. occidental boundaries for the species cited by Cei (1993). In a previous work (Cei 1986), the southern limit for *P. patagoniensis* is stated as "no more south than Rio Negro-Chubut boundaries" and a locality record is shown on the distribution map of the species near the record reported herein. Nonetheless, this is the first vouchered record for southern Rio Negro province.

While conducting field surveys in valleys of the Andes in the state of Mérida, Venezuela, new amphibians records were documented. Voucher specimens were deposited at the Universidad de Los Andes Vertebrate Collection (CVULA), the Zoological Museum Collection of the Universidade Estadual de Campinas (ZUEC), and the University of Kansas Museum of Natural History (KU).

Adenomera andreae. ESTADO TÁCHIRA: Municipio Uribante: Campamento Siberia (7°53'N, 71°45'W), 1000 m. 28 May 1990. ZUEC 9134. J. E. Péfaur, N. M. Sierra and F. Godoy. Verified by A. J. Cardoso. First Andean record and the westernmost record in Venezuela (Heyer 1973; Péfaur and Díaz de Pascual 1987). Barrio (1998) indicated the presence of this frog in the state of Trujillo (without supporting data).

Hyla microcephala. ESTADO MÉRIDA: Municipio Tovar: Hacienda Cucuchica (8°20'N, 71°44'W), 7 km NE Tovar, 750 m. 29 July 1995. CVULA 5727 and 18 February 1996. ZUEC 9729. N. M.

Sierra and J. E. Péfaur; Municipio Libertador: Mérida (8°35'N, 71°18'W), 1650 m. 2 January 1996. CVULA 5789. N. M. Sierra and J. E. Péfaur; ESTADO TÁCHIRA: Municipio Uribante: Valle del Río Doradas, II Desarrollo de CADAFE (7°48'N, 71°45'W), 650 m. 29 May 1990. ZUEC 9139. J. E. Péfaur, N. M. Sierra and A. Castillo. All verified by A. J. Cardoso. In addition to being the first Andean records, these are elevation records for the species (Rivero 1961; Péfaur and Díaz de Pascual 1982; Barrio 1998).

Scinax rostratus. ESTADO MÉRIDA: Municipio Tovar: Hacienda Cucuchica (8°20'N, 71°44'W), 6 km NE Tovar, 700 m. 9 December 1995. CVULA 5734, ZUEC 9733, KU 223374. N. M. Sierra and J. E. Péfaur. Same locality. 24 June 1996. CVULA 5785. Jaime E. Péfaur. All verified by W. E. Duellman. First record for state and westernmost in Venezuela (Rivero 1968; Duellman 1972; La Marca 1992; Hero and Mijares-Urrutia 1995; Yústiz 1996; Barrio 1998).

Flectonotus pygmaeus. ESTADO MÉRIDA: Municipio Tovar: Hacienda Cucuchica (8°19'N, 71°44'W), 9 km NE Tovar, 800 m. 28 January 1996. CVULA 5699. N. M. Sierra and J. E. Péfaur. Same locality. CVULA 5786. J. E. Péfaur. Both verified by Jesús Manzanilla-Puppo. Mijares-Urrutia and Arends (1993) erroneously indicated a record for the state of Falcón as the westernmost in Venezuela. Previously, Duellman and Gray (1983) had reported this species as present in the three westernmost states of Venezuela: Barinas, Mérida, and Táchira.

Eleutherodactylus lentiginosus. ESTADO MÉRIDA: Municipio Tovar: Hacienda Cucuchica (8°20'N, 71°44'W), 7 km NE Tovar, 800 m. 20 August 1995. ZUEC 9728, 9734. Same locality. 6 August 1995. CVULA 5731. Verified by J. D. Lynch. First state record and easternmost in the Andes (Rivero 1982; La Marca 1992).

Physalaemus pustulosus. ESTADO MÉRIDA: Municipio Andrés Bello: 10 km NW La Azulita, vía Caño Zancudo (8°45'N, 71°28'W), 700 m. 16 June 1990. CVULA 5728. A. J. Cardoso and J. E. Péfaur. Municipio Pinto Salinas, 3 km NE Santa Cruz vía La Victoria (8°25'N, 71°38'W), 600 m. 8 May 1995. CVULA 5729. J. E. Péfaur. Municipio Tovar: Hacienda Cucuchica (8°20'N, 71°44'W), 6–9 km NE Tovar, 700–810 m. 24 July 1995. CVULA 5730, ZUEC 9732. 18 December 1995. CVULA 5731. N. M. Sierra and J. E. Péfaur. All verified by A. J. Cardoso. These are elevation records for the species.

With the exception of *Flectonotus pygmaeus* and *Eletherodactylus lentiginosus*, the rest of the species are common in the lowlands of Venezuela. The members of these higher populations inhabit marshes or temporary ponds located in places where the primary submontane rain forest has been cut and/or has been replaced by pasture. Furthermore, most localities reported herein are along Andean river valleys in the northwestern versants facing the Maracaibo Lake basin. Usually, these and other anuran species reach higher elevations in the northwestern rather than in the southeastern versant of the Venezuelan Andean Cordillera.

Acknowledgments.—We are indebted to the late Adão J. Cardoso, William E. Duellman, John D. Lynch, and Jesús Manzanilla-Puppo for their help at different stages of this research. Marisela Angelino, Alba Díaz, Celyanabel Valdés, and Alberto Veloso were helpful in logistics. This report is part of the CDCHT C-805-96 and CONICIT I-011 projects directed by the senior author.

e-mail: jacqueline.webb@villanova.edu

What happens when simple observations made by a group of school kids on a field trip are transformed into awareness of a phenomenon of potential worldwide importance? *A Plague of Frogs* is not just a herpetological tale. It is a well-told and well-documented story of natural history, science, and environmental politics. In *A Plague of Frogs*, William Souder, an award-winning freelance journalist, tells the complex and interesting story of the startling discovery of limb deformities in frogs and the multifaceted investigations into their causes.

In 1995, limb deformities were found in the frogs in Ney Pond in Minnesota. They had missing legs, non-functional legs, extra legs, undersized legs, legs twisted like cork screws, legs attached to the body by webbing. Soon, state and federal agencies initiated investigations into the causes of these deformities and then they were found in other states and in Canada. Interestingly, such deformities are not new—the author notes that records of their occurrence are in the literature from as early as 1740. Today, with awareness of local and global environmental crises, including the worldwide declines in amphibian populations, the questions were straightforward: Are these naturally occurring abnormalities, or were they caused by one or more environmental factors? As the story proceeds, we find out that the general consensus is that the deformities are likely to be caused by environmental factors. Both parasites and chemical contaminants (including pesticides) were shown to cause limb abnormalities in laboratory experiments. Unfortunately, a single environmental cause and underlying developmental/biochemical mechanism could not be identified to account for the diversity of abnormalities observed. After describing all the available evidence, and the experimental data generated to explain the appearance of the deformities through 1999, the book concludes with the idea that limb deformities are the result of the synergism of multiple environmental factors (e.g., parasites, chemical contaminants) acting through multiple mechanisms (e.g., mechanical or biochemical disruption of limb development), and/or the local manifestation of larger global phenomena (e.g., global climate change, increase in UV radiation).

The book is divided into two parts and fourteen chapters. The book is written largely in chronological sequence, which effectively shows science as an intellectual process, and how it is affected by the complexities of politics and personalities. The book reads like an expanded journalistic exposé. This is not suprising, since Souder first reported on the discovery of deformed frogs in *The Washington Post*. Souder tells a good story by gradually adding new information in a way that accurately reflects the course of events, but also provides maximum impact for the reader. He had exclusive access to all of the key players: landowners, government officials and environmental scientists, researchers, and a varied cast of research scientists. He becomes intimately involved in the development of the story not only as storyteller, narrator, interviewer, and observer, but as participant, wader-wearing field assistant, critical reviewer, occasional consultant, and commentator on people and personalities.

Most importantly, Souder clearly communicates the facts and principles underlying the scientific issues at hand. Throughout the first half of the book, he pauses to give remarkably good minilectures on tadpole biology (p. 62), deep evolutionary time (p. 70), evolution of the vertebrate limb (p. 72), cell differentiation and the development of the limb (p. 88), retinoic acid mimics and endocrine disruption (p. 92), and standard assays for chemical contaminants (p. 119). He communicates the essential concepts and provides factual material without resorting to those cute, often trite, analogies that many other writers have used to appeal to the lay reader. He also uses engaging and well-constructed re-tellings of conversations with research scientists and government administrators, and of the proceedings and often colorful debates at scientific conferences as vehicles to explain the different and often conflicting hypotheses for the appearance of limb malformations (e.g., parasites, endocrine disruption) and its potential link with the overall decline in amphibian populations (e.g., UV radiation, the extinction of the golden toad). Throughout the book he is very careful to define scientific terminology, with the clear understanding that he is a non-scientist talking to non-scientist readers. Souder carefully presents the different hypotheses to explain the occurrence of limb deformities, and the data and ideas that support and refute them. He emphasizes the difficulty of evaluating conflicting and sometimes overlapping hypotheses. He also demonstrates a clear understanding, and even compassion, for the people involved, and an appreciation for the problems that arise when the scientific process is overshadowed by personalities, resulting in serious issues of scientific credibility. The nine pages of bibliographic sources, presented at the end of the text, include major textbooks and primary journal articles and provide evidence of the tremendous amount of research that went into the writing of this book.

The story of limb deformities in frogs is a complex one. There are many participants at various levels of the private, scientific, and government sectors, and the answers to the scientific questions posed are not as satisfyingly simple and elegant as one might hope. But, it is the complexity of the story that makes this book an excellent teaching tool for courses in introductory biology, environmental science, scientific ethics, and of course, herpetology. In the process of trying to unravel the complexities of the problem of limb deformities, Souder touches upon a myriad of fundamental issues including: the value of the scientific method as a process, the search for patterns in data and the appropriate use of statistics, ownership of data, the importance of seaching the literature in languages other than English, the importance of communication among scientists, natural history as a source of "natural experiments" that may be informative, the use of correlation versus cause and effect in hypothesis testing, how multiple hypotheses are generated by different people who have observed the same phenomenon through different filters, the value and frustration of being

presented with multiple explanations for what appears to be a single phenomenon, and how the presentation of results can influence the public's perception of a problem. The author also makes several interesting comments on the need for organismal biologists in a world where the "ascendency of molecular biology [is] reducing interest in the natural history of whole organisms to the vanishing point" (p. 139), where "biologists who study animals...are on their way out," and where "zoologists... are an endangered species." In other words, if this trend continues, who will be left to unravel the next mystery?

The book would have benefited from the inclusion of one or more maps of Minnesota and North America to show the approximate locations of the sites where the different types of limb deformities have been found. In addition, the second half of the book could have benefited from additional editing. There were some textual redundancies above and beyond those needed for clarity, and for jogging the memory of the reader. I found myself struggling between anticipation of the punchline and my recognition of the need for a detailed treatment of the development of the scientific ideas and approaches necessary to explain the underlying causes of the limb deformities. It is only in the last few chapters that the story appears to accelerate with the presentation of experimental evidence to support the hypotheses presented. By the last chapter, there is a crying need for an explicit restating of the major scientific issues, conflicting hypotheses and their authors, the data presented to support them, and tentative conclusions (a summary table would have been nice). I admit, even upon writing this review, that I needed to go back for a second reading to pull out the essential questions (and answers) in a concise, presentable way that would be appropriate for a lecture on the subject.

This well-written and informative book is highly recommended for the scientists (specialists and non-specialists) and lay readers who are interested in environmental issues and global biodiversity.

Ecología de los Vertebrados de Chile, by Fabián Jaksic. 1996 [1997]. Ediciones Universidad Católica de Chile, Santiago. 262 pp. Softback. ISBN 956-14-0440-0.

JAIME E. PÉFAUR
Grupo de Ecología Animal, Facultad de Ciencias
Universidad de Los Andes, Mérida, Venezuela
e-mail: pefaur@ciens.ula.ve

One of the main features of South America is its great biodiversity. The whole territory, north to south, east to west, both terrestrial and aquatic, has an incredible diversity of flora and fauna. Five of the countries included in this continent are considered megadiverse in a worldwide context. Six others have a quite high biotic diversity, but two—Chile and Uruguay—have rather small faunas and floras compared to the rest. The herpetofauna of Chile includes about 42 amphibians and 90 reptiles (Formas 1995; Veloso and Navarro 1988), and that of Uruguay includes 40 species of amphibians (Klappenbach and Langone 1992) and 64 reptiles (Langone, pers. comm.). For comparison, Venezuela has approximately 252 amphibians and 300 reptiles (Péfaur 2000). In Chile, there are no salamanders or caecilians; and reptiles are largely represented by lizards, with a handful of snakes and marine turtles and no crocodilians.

Although restricted, the herpetofauna of Chile has had a significant and fruitful history of study. The early comprehensive works of Cei (1962) and Donoso-Barros (1966) established an excellent base for taxonomic studies of the anurans and reptiles, respectively. Once the most basic taxonomic problems of the herpetofauna had been resolved, the logical next step was to study its ecology. The small size of the Chilean herpetofauna, a result of temporal and geological isolation, benefited the country's student community by providing an excellent natural laboratory where endemism, restricted geographical distribution, a relatively clear separation of biomes and ever-present latitudinal and altitudinal gradients, are the most relevant ecological factors. The result was a quite large assembly of ecological researchers producing keen, in-depth studies on the country's biota.

Ecología de los Vertebrados de Chile is a university text intended to illustrate the vertebrate ecology of the country through a review of the primary literature. In a total of 262 pages, covering 11 chapters and an extensive bibliography, the ecology of five vertebrate classes is treated in sections devoted to biodiversity, autecology and ecology of populations, and community ecology. Amphibians are treated in six pages, and reptiles in 22 pages. Fifty-seven pages are devoted to the bibliography.

Jaksic's chief approach is to review the pertinent ecological literature published mainly in Chile. About 1130 references are used to analyze the ecology of the Chilean vertebrates, with about 60 related to amphibians and 180 pertinent to the reptiles.

Ecological data of Chilean amphibians are scarce—in six pages all the relevant ecological knowledge is summarized. Information about taxonomy, distribution, conservation, ecophysiology, ethology, reproduction, diet, and natural history are provided for some populations and species and niche relationships, species gradients in altitudinal transects, and comparison of continental assemblages are treated in the context of community ecology. However, the handling of information is uneven. For instance, Jaksic indicates that the ecophysiology of the Chilean anurans is almost unknown, but relatively detailed information is given for ecophysiological aspects of several species, most notably *Caudiverbera caudiverbera*, *Bufo chilensis* and *B. spinulosus*. Information is also provided about niche partitioning between *Alsodes tumultuosus* and *A. montanus*, two sympatric species of high Andean leptodactylid anurans. On the other hand, the behavioral ecology and trophic relations of frogs are each covered only by a short sentence.

The reptile chapter follows the same general arrangement as that dealing with frogs, but each section is subdivided, reflecting the more detailed information available for this group. This chapter provides a vast and rich accumulation of data. The references about taxonomy are diverse, but cover mainly the 1980s and 90s. A few additional references are provided for the distribution and conservation of reptiles. The bulk of the ecological information about this group is at the population and community levels. Many of the reptile references are by Jaksic himself, who with his associates and students, has wisely chosen the genus *Liolaemus* to develop, test, and probe ecological theories.

Liolaemus is the most important reptile group in Chile, accounting for more than 50 species or about 60% of the total number of

reptiles. Speciation of these medium-sized lizards is explained by Fuentes and Jaksic (1979) as a result of Pleistocene climatic and environmental changes. Many ecological attributes of this genus have been researched, as is shown by the data presented on, for example, morphological adaptations to elevation, thermoregulation, and dietary changes as adaptations to different environments. The inclusion of relatively few studies of restricted scope based on other lizards highlights the significance of the ecological studies on *Liolaemus*. *Liolaemus* has also been studied in the context of community ecology to examine such patterns as morphological correlates of microhabitat segregation, competition and predation, as well as species replacement in elevational transects. Herpetologists should not ignore the other chapters of the book. That dealing with birds of prey is rich with information about the important role played by *Liolaemus* species as dietary items.

Based on the data presented, it seems that the bulk of the present knowledge of Chilean reptile ecology is derived from lizards and that far less is known about other groups. The ecology of snakes, for instance, is covered by no more than four references, which together hardly provide a sound basis.

I found that the book gathers together most of the ecological information available for Chilean amphibians and reptiles and that the data provided for the rest of the vertebrates are also well documented. Jaksic's goal of summarizing empirical studies to provide a sound basis for the teaching of a course in vertebrate ecology is achieved admirably. Although some references have been omitted, the work of collating and synthesizing has been done carefully and thoughtfully. Anyone teaching about or studying the Chilean herpetofauna will find the majority of the key references dealt with in this volume.

This book reflects the energy and vitality of the Chilean ecological community. In addition to Jaksic and his associates, a variety of other researchers have worked and continue to work to expand the knowledge base on Chilean vertebrate ecology. This book reflects the successful efforts of the dedicated student community in Chile to move the study of the natural history and ecology of Chilean vertebrates from modest beginnings to a world class level. In my opinion, only the efforts of Janzen (1983) and associates to the study of the Costa Rican vertebrates are comparable in Latin America to the Chilean situation. It is a testament to Chilean biologists that several important journals are produced in that country. For example, references to Revista Chilena de Historia Natural, Medio Ambiente, and Boletín del Museo Nacional de Historia Natural appear on every page of the bibliography, reflecting both the high quality and quantity of scientific output. Although the Chilean amphibians and reptiles are not especially numerous, they, along with the other vertebrates of the country, have proved to be excellent models for the solid ecological research reviewed in *Ecología de los Vertebrados de Chile*.

North American Box Turtles: A Natural History

BY **C. Kenneth Dodd, Jr.**

Native to the United States and Mexico, the box turtle is so named because of its box-like appearance. A once familiar backyard visitor, the box turtle is also the focus of both conservation efforts and biological research.

North American Box Turtles is the first book-length natural history of the twelve species and subspecies of the terrestrial box turtle. It includes comprehensive information on the species' systematics, evolution, habitat use and activity patterns, behavior, courtship and reproduction, diet, population structure, and disease. Each chapter discusses conservation applications as well as the need for long-term data, monitoring, and viewing box turtles within a landscape context.

Special features of this book include:

- color photos of all species and subspecies and habitats
- a simplified identification guide to both living and fossil species
- a summary of information on fossil Terrapene and Native uses of box turtles
- end-of-chapter sections that highlight future research directions
- a glossary of general natural history terms
- a bibliography of literature on box turtles
- 48 color and 43 b&w illustrations

$59.95 HARDCOVER

All royalties from the sale of this volume will go to the Chelonian Research Foundation, a nonprofit foundation for the conservation of turtles.

CHELONIAN RESEARCH MONOGRAPHS, NUMBER 2

Now Available

Chelonian Research Foundation is pleased to announce the publication of the second volume of *Chelonian Research Monographs*, published August 2000:

ASIAN TURTLE TRADE:
Proceedings of a Workshop on Conservation and Trade of Freshwater Turtles and Tortoises in Asia

Edited by

PETER PAUL VAN DIJK, BRYAN L. STUART, AND ANDERS G.J. RHODIN

This timely and critically important volume documents the trade in non-marine chelonians for the Asian food and medicinal markets, presenting the results of a regional workshop on Asian turtle trade held in Phnom Penh, Cambodia, in December 1999. The 164-page volume is available in hard or soft cover and encompasses 22 papers by 45 contributors and includes over 50 full-color photographs.

Both hard and soft cover editions are available for immediate delivery.

Table of Contents

Executive Summary
Introduction
- The status of turtles in Asia.
- An overview of Asian turtle trade.

Northeast Asia Region (China, Hong Kong, and Taiwan)
- Conservation and trade of terrestrial and freshwater turtles and tortoises in the People's Republic of China.
- Trade and conservation of turtles and tortoises in the Hong Kong Special Administrative Region, People's Republic of China.
- Current status and utilization of chelonians in Taiwan.
- Turtle trade in northeast Asia: regional summary.

Indochina Region (Cambodia, Laos, and Vietnam)
- Overview of turtle trade in Cambodia.
- Conservation status and trade of turtles in Laos.
- Status and conservation of tortoises and freshwater turtles in Vietnam.
- Turtle trade in Indochina: regional summary.

South Asia Region (Bangladesh, India, and Myanmar)
- Trade and conservation status of turtles and tortoises in Bangladesh.
- Status information on the tortoises and freshwater turtles of India.
- Exploitation and conservation status of tortoises and freshwater turtles in Myanmar.
- Turtle trade in south Asia: regional summary.

Southeast Asia Region (Indonesia, Malaysia, Papua New Guinea, and Thailand)
- Freshwater turtle and tortoise conservation and utilization in Indonesia.
- Export of live freshwater turtles and tortoises from North Sumatra and Riau, Indonesia: a case study.
- Freshwater turtle and tortoise utilization and conservation status in Malaysia.
- Conservation status of freshwater turtles in Papua New Guinea.
- Conservation status, trade, and management of tortoises and freshwater turtles in Thailand.
- Turtle trade in southeast Asia: regional summary.

Summary
- Conclusions and recommendations.

Appendix
- Recommended changes to 1996 IUCN Red List status of Asian turtle species.

ECOTOXICOLOGY OF AMPHIBIANS AND REPTILES

Donald W. Sparling, Greg Linder, Christine A. Bishop, Editors

This state-of-the-science review and synthesis of amphibians and reptiles ecotoxicology demonstrates the interrelationship among distribution, ecology, physiology, and contaminant exposure, and interprets these topics as they pertain to comparative toxicity, population declines, malformations, and risk assessment. In this way, the book identifies and serves as a basis for the most pressing research needs in the coming years.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, and Legislation & Conservation should be sent directly to the appropriate section editor. Send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, Herpetological History, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without consulting the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700	$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages	$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages	$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)	$35
INCOMPLETE SET: NUMBERS 1 – 190	$75
191 – 410	$85
411 – 700	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2001 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 27–31 July 2001

Society for the Study of Amphibians and Reptiles
2001 Annual Meeting

together with

The Herpetologists' League

27 – 31 July 2001
University Place Conference Center and Hotel
Indianapolis, Indiana, USA

Keynote Address: "Herps and Hopes: Africa in a New Millenium," by Bill Branch, The Hepetologists' League Disntiguished Herpetologist for 2001 (Port Elizabeth Museum).

Symposium: "Amphibian Population Declines." *Organizers:* David M. Green, McGill University (czdg@musica.mcgill.ca) and Karen Lips, St. Lawrence University (klip@music.stlawu.edu).

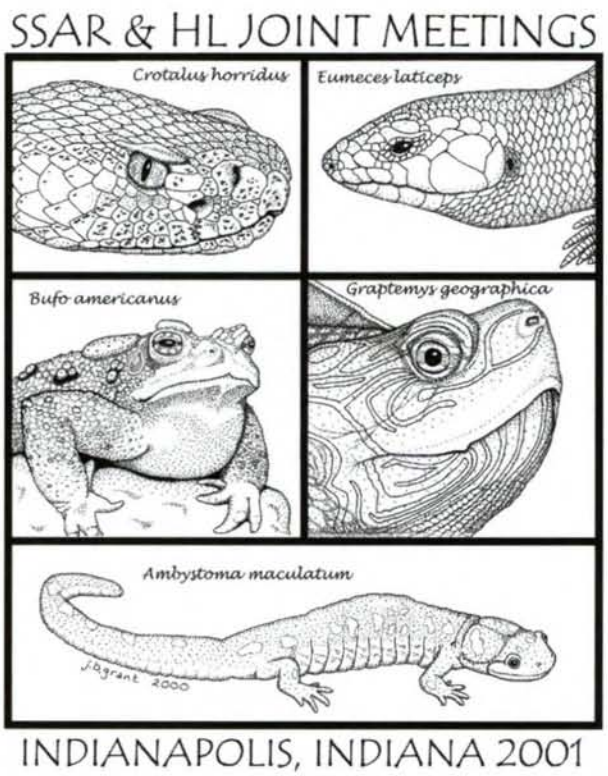
Symposium: "Herpetological Research in Zoos: The Academic Connection." *Organizers:* John D. Groves and Hugh R. Quinn, Cleveland Metroparks Zoo (hquinn@ix.netcom.com).

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

Student Travel Awards: Ten Sherman A. Minton student travel grants of US $200 each will be available for SSAR members. Refer to page 201 of the December 2000 issue of *HR* for details.

Student Paper Awards: Henri Seibert prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the official Meeting Announcement for details.

Social Activities: General Reception in the University Place Ballroom, SSAR Herp Silent Auction, Graduate Student Reception, Sunday night Barbecue Dinner and Auction, Graduate Student Reprint & Book Scavenge, Herpetological Quiz.



Multimedia Presentations: "Amphibians of the Appalachians," and "Herpetology of the West," by David Dennis and Eric Juterbock. President's Travelogue slide presentations by Patricia Burrowes (Puerto Rico), Tim Halliday (South Africa), John Wilkinson, Ross Alford (Australia), Hinrich Kaiser (Southeast Asia), and Michael Lannoo (Antarctica).

Live Animal Exhibit: Live amphibians and reptiles of Indiana will be on display and available for photography.

Costs: Preregistration US $240 regular, US $175 student, US $120 accompanying person. After June 1, 2001, costs are US $295, US $200 student, US $145 accompanying person.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Further Details: Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of the participating societies. Overseas members wishing to receive this information may do so by contacting Henry R. Mushinsky, Local Chair, Department of Biology, University of South Florida, Tampa, Florida 33620, USA; e-mail: mushinsk@chuma1.cas.usf.edu or telephone 813/974-5218. Please visit the meeting web site at http://www.ukans.edu/~ssar/ind.html for additional and updated information.

About Our Cover: *Agalychnis annae*

Hylid frogs of the genus *Agalychnis* are among the most colorful animals of neotropical rainforests. One species, *A. callidryas*—said to be the most-photographed amphibian—is something of a "poster frog" for rainforest conservation. Other species in the genus remain less well known, however. Among these, *A. annae* is known from a few sites on the Atlantic slopes of Isthmian Central America in moist and wet tropical forest types, up to about 1600 meters elevation (Duellman 1970. The Hylid Frogs of Middle America. Univ. Kansas Mus. Nat. Hist., Monogr. No. 1, xi + 753 pp., 72 plates). At higher elevations, *A. annae* is most commonly encountered along forested streams, and it still occurs in some parts of the city of San José, Costa Rica.

There are eight species in the genus *Agalychnis*, collectively known as "leaf frogs." *Agalychnis*, along with five other genera, comprise the subfamily Phyllomedusinae of the treefrog family Hylidae. Phyllomedusines range from Mexico through Central- and tropical South America.

Leaf frogs live in the canopy and are subject to dessication. To combat this, they secrete a waxy substance which is wiped over the dorsal surfaces before daybreak. When at rest, the limbs are adpressed to the body, reducing the area exposed to drying. These frogs are colored and patterned to resemble the green leaves on which they sleep, thereby reducing the risk of detection by tree-dwelling predators such as monkeys. When perching on leaves, they reflect near-red light in the infrared spectrum, just as do the leaves (Schwalm et al. 1977. Science 196:1225–1227).

Phyllomedusine frogs come down from the canopy to breed. Most species congregate around small forest pools of quiet water, although some breed only in flooded stumps and similar situations. The male advertisement call is typically a somewhat muted "tok" although a large chorus of some species can often be heard at some distance in the forest at night.

Females are larger than males and often are the objects of much attention during breeding aggregations. Males will wrestle with one another in their attempts to mate with an available female. An arboreal nest is constructed by rolling a leaf and depositing an adherent egg mass within. Upon hatching, the larvae ooze from the gelatin and fall into the water, where they develop as tadpoles.

The eggs of leaf frogs are preyed upon by cat-eyed snakes of the genus *Leptodeira*. These arboreal colubrids are always present during phyllomedusine breeding aggregations and are adept at locating and engulfing the egg clutches. Calling males are subject to predation by bats in the genus *Trachops*, which locate their prey by sound.

The specimen on our cover was collected by **Louis Porras** in August 1977 from his home town of San Ramón, Costa Rica. It was photographed on a tabletop in Miami, Florida that same month by **Jim Bridges** (Herpeto, Inc., Hollywood, Florida), using a Canon F1 with a FL 50mm f3.5 macro lens and Kodachrome 25. The lighting was provided by a 400-watt second Norman studio strobe unit, with two flash heads. Each head was bounced off a silver umbrella to produce a soft rainy day-style lighting. As he does for all of *HR*'s covers, Bridges handled the separation and imaging of this photograph as well. Jim is well known in the herpetological and herpetocultural publishing fields, but the majority of his photographic work has been published in books and non-herp magazines, for such organizations as the National Geographic Society, National Wildlife Federation, and Sierra Club.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (becoming President in 2003) ..... Janalee Caldwell.
Secretary ..... John Matter (unopposed).
Treasurer ..... Robert Aldridge (unopposed).
Board of Directors (Class of 2003) ..... Linda Ford and Lee Fitzgerald.

Items Needed for SSAR/HL Auction at Indianapolis

The SSAR/HL Auction will be conducted during the joint annual meeting of the Society for the Study of Amphibians and Reptiles and The Herpetologists' League, at the University Place Conference Center and Hotel, Indianapolis, Indiana, July 2001. All proceeds from the auction will be shared equally between SSAR and HL, and will help to continue the production of the diverse publications and services for which the societies are known. Items of value, as well as those of a humorous nature, are welcome as we once again endeavor to separate auction participants from their money through the judicious use of beer and plastic. Auction items may be brought directly to the meeting or sent in advance to: *Dr. Craig E. Nelson, Department of Biology, Jordan Hall 142, 1001 E. 3rd St., Indiana University, Bloomington, Indiana 47405-3700, USA.*

Final Report on the Auction of Joseph R. Bailey's Herpetological Library

SSAR is very pleased to report the final results of its auction of the late Joseph R. Bailey's herpetological library. The auction was announced in the September 1999 issue of *Herpetological Review*. The library was donated to the Society by Professor Bailey's widow. She did so in order to support projects of interest to her husband, in particular, his interest in student research activities and the production of new books. The Board of Directors has established the Joseph R. Bailey Endowment, and interest income from this investment will be used to support these programs in perpetuity.

A total of 374 lots (books and monographs) were auctioned by post. Eighty-four persons (72 in North America, 9 Europe, 2 in Australia, 1 in South America) submitted more than 1600 bids; 79 of the 84 were successful for at least one lot. A detailed account of the auction was published in the December 2000 issue of *Newsletter and Bulletin of the International Society for the History and Bibliography of Herpetology* (for subscription, contact Richard Wahlgren: Richard.Wahlgren@skanska.se). In addition to the public auction, Professor Bailey's collection of herpetological reprints was sold *en bloc* to a dealer.

Total income from the sale of Professor Bailey's herpetological library was $24,532 (books $18,400; reprint collection $6,132). The expenses (postage, printing of lists, telephone, etc.) were $1,287, or 5.2% of the gross income; thus $23,245 has been placed in the Bailey Endowment.

The Society, on behalf of the herpetological community, is greatly indebted to Mrs. Bailey and her family for their generosity. This is the first endowment in SSAR to be established in honor of a former member (Professor Bailey was a member of OHS–SSAR from the earliest days) and it will be our pleasure to regularly associate his name with various Society activities. We also acknowledge with appreciation the volunteer work of Steve Busack and Linda and Bob Aldridge in carrying out the mechanics of the auction.

NEWSNOTES

EMBL Reptile Database: Online Library, CD-ROM

Starting in January 2001, the database now offers a selection of historical reptile papers as PDF files. As a pilot project, about 60 papers from the *Proceedings of the Academy of Natural Sciences of Philadelphia*, published between 1841 and 1899, have been posted on our website. Another 60 will follow in the second quarter of 2001, completing the set of 127 reptile papers that have been published during that time period in the *Proceedings*. Scanning and conversion to PDF files of the reptile papers from the *Annals and Magazine of Natural History (1838–1899)* is currently under way and will be financed by the sale of CD-ROMs. The CD-ROM contains the Reptile Database as a user-friendly application and all reptile papers from the *Proceedings* (March 2001) and is available for US$ 25 on Windows and Macintosh systems. The CD-ROM is free for contributors. For more details visit the web site at http://www.embl-heidelberg.de/~uetz/LivingReptiles.html.

Kansas Herpetological Society Annual Meeting

The Kansas Herpetological Society held its 27th Annual Meeting at the Adam's Mark Hotel in Kansas City, Missouri, USA, on 21–22 October 2000. The meeting was co-hosted by the Missouri Herpetological Association and the Kansas City Herpetological Society. Over 125 participants attended scientific paper sessions to listen to 34 talks on amphibians, turtles, and reptiles by scientists and students from across the nation.

During its business meeting, the KHS voted Suzanne L. Collins (The Center for North American Amphibians and Reptiles, Lawrence) as President-elect, Eric Kessler (Blue Valley North High School) as Treasurer, and Mary Kate Baldwin (Topeka Collegiate School) as Secretary. Mark Ellis (Topeka) took office as President on 1 January 2001. Robert Powell (Avila College) served as President during 2000, and hosted the meeting this year.

Also during the Society business meeting, Powell awarded Kevin Aldrich, a graduate student at Emporia State University, the 2000 Howard K. Gloyd/Edward H. Taylor Scholarship. The scholarship honors the memory of two great biologists with strong ties to Kansas. Gloyd was born in Ottawa and attended both Kansas State University and the University of Kansas, and Taylor graduated from Garnett High School and was a biology faculty member for many decades at the University of Kansas, Lawrence.

The business meeting concluded after Kelly J. Irwin, former KHS president and currently the state herpetologist of Arkansas, presented Eric M. Rundquist, University of Kansas, with the Bronze Salamander Award, the highest recognition given by the Society for distinguished service. Rundquist served as KHS editor for the past decade, and was one of the founding members of the Society.

Prior to the Saturday night KHS auction, Emily C. Moriarty, a graduate student at the University of Texas, Austin, was chosen as the third recipient of *The Suzanne L. and Joseph T. Collins Award for Excellence in Kansas Herpetology.* Moriarty is a former Lawrence, Kansas, resident, and recently graduated with honors from St. Mary's College in Notre Dame, Indiana. At the KHS Silver Anniversary Meeting in 1998, she presented a lecture on the molecular systematics of Western Chorus Frogs in Kansas, and her presentation was judged by the society as the best research on the Kansas herpetofauna during the preceding two years (1998 and 1999). For her work, Ms. Moriarty was given a plaque and a check for $1000.00 by Robert Powell and Travis W. Taggart, Fort Hays State University. *The Collins Award* is the largest biological award given annually in the state of Kansas, and the largest annual presentation made nationally to further research on (even-numbered years) or photography of (odd-numbered years) amphibians, turtles, and reptiles.

Following the first Sunday morning scientific paper session, two other KHS meeting attendees were recognized as the second annual recipients of *The Big Croaker Awards,* sponsored by the Kansas Department of Wildlife and Parks and the Kansas Amphibian Monitoring Program. Established in 1999, the awards are given to those individuals who monitored choruses of frogs and toads with diligence and excellence during the spring of 2000. Margaret Stewart, of Manhattan, Kansas, and Keith Coleman, of the University of Kansas, Lawrence, were each given a commemorative certificate and a check for $100.00 by Linda Weir, coordinator of the North American Amphibian Monitoring Program, Laurel, Maryland, and Ken Brunson, representing the Kansas Department of Wildlife and Parks. Each spring, over 100 KAMP volunteers census choruses of amphibians on over eighty 15-mile routes across Kansas, establishing baseline information that will eventually be used to determine whether amphibian populations are declining, increasing, or remaining stable.

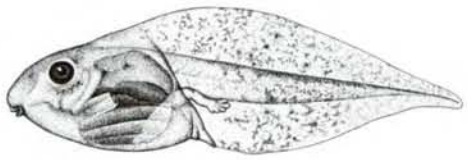
Featured speakers at the two-day event were Robert Wilkinson (Southwest Missouri State University, Springfield), Henry S. Fitch (University of Kansas, Lawrence), Walter Meshaka (State Museum of Pennsylvania, Harrisburg), Ronald Goellner (St. Louis Zoo), Robert W. Henderson (Milwaukee Public Museum), Dwight R. Platt (Bethel College, North Newton, Kansas), Lee Grismer (La Sierra University, Riverside, California), and Robert Aldridge (Saint Louis University).

In 2001, the Society will meet in Topeka, Kansas.

A New Book from the Society for the Study of Amphibians and Reptiles

THE HYLID FROGS OF MIDDLE AMERICA

New and Expanded Edition



by WILLIAM E. DUELLMAN

illustrated by David M. Dennis

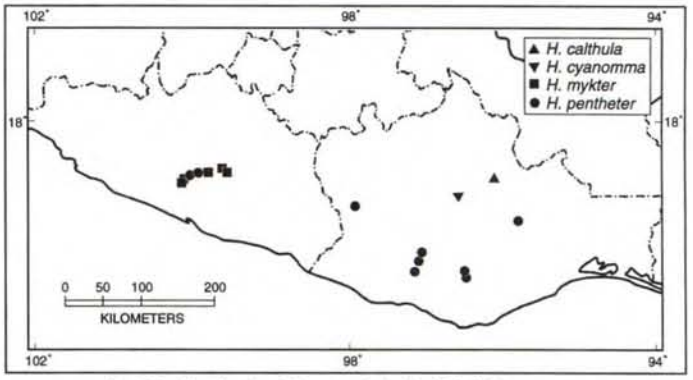
This is a product that current and future researchers will cherish. . . . No one is as knowledgeable, as attentive to organization and detail, and as thorough. . . . Throughout the entire work, high emphasis is placed on quality—accurate data, excellent photography, wonderful artistry. . . . This book has much to tell us concerning the unique amphibian fauna of the region, and will long serve as the fundamental reference source for the hylids.
— DAVID B. WAKE, from the Foreword to the New Edition.

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES IS proud to announce the publication of a new and expanded version of a book that has long enjoyed a classic status. Professor Duellman's *Hylid Frogs* was originally issued in 1970 by the Museum of Natural History of The University of Kansas. As Jay M. Savage wrote in *Herpetological Review* at the time, "In tropical American herpetology, it is likely to remain an unassailable model."

In 753 pages, 324 figures, and 72 plates, the original book surveyed all 115 species of hylid frogs then known from Mexico to Panama, complemented by reproductions of David M. Dennis's highly detailed and life-like watercolors. Hobart M. Smith commented in *Copeia*, "*Hylid Frogs* marks an apogee of achievement; it is the Hope Diamond of technical herpetological literature." The book was an instant success, but it soon went out of print and copies today fetch $300 or more on the secondhand market, when they can be found at all.

During the intervening years until the present, the number of species in this region has risen by 50 to 165, most of them new species from southern Mexico, Guatemala, and Honduras, and all of them from the highland regions. **The expanded edition consists of 1170 pages—a 55% enlargement of the original—and 20 new plates.** The new edition includes a reprint of the original text plus a supplement in which each species account is revised and the new or resurrected species are treated in detail. Similarly, the numbers of figures, tables, and appendices are significantly increased. New spot distribution maps are provided for the new species and also for many others whose distributions have expanded since 1970.

For reproduction of the color plates, **the original watercolors have been laser scanned—not photographically reproduced as in 1970—using the latest technologies.** This has produced images that are brighter, more accurate, and much closer to the original paintings. In addition, Mr. Dennis has produced 55 new watercolors (51 in color, 4 black-and-white). The resulting plates are of the highest standard.



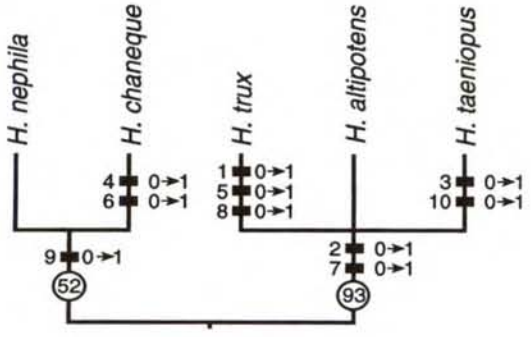


FIG. 402. Distribution of four species in the *Hyla bistincta* group.

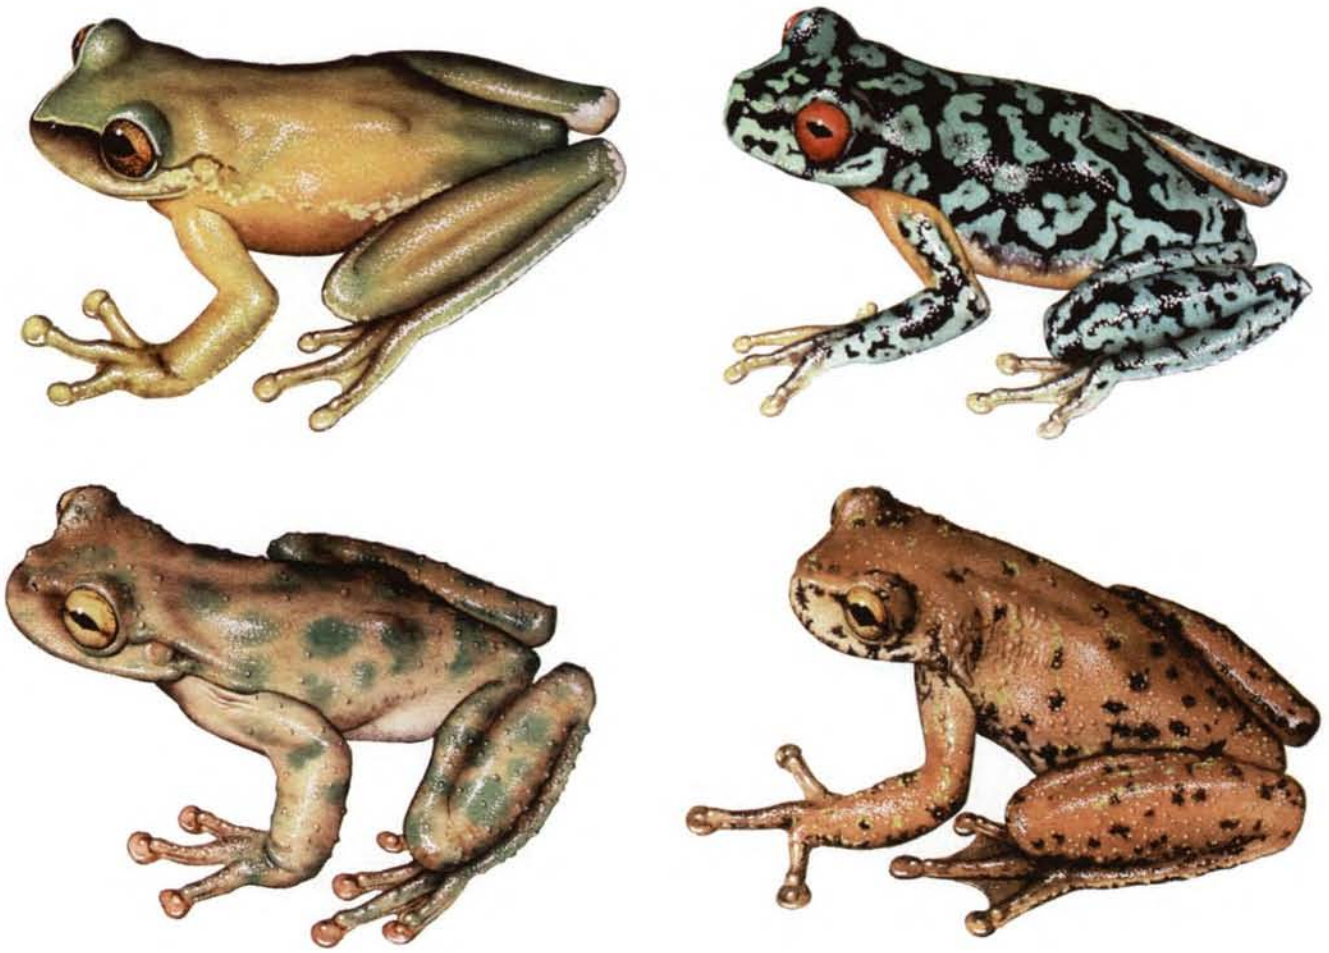

The species accounts are arranged as in the 1970 edition: Synonymy, Diagnosis, Description, Tadpoles, Mating Call, Natural History, Remarks, Etymology, and Distribution. There is a review of the evolutionary history of Middle America including plate tectonics, the evolution and phylogenetic relationships of hylid frogs, a chapter on distribution and diversity, and biogeographic comparisons between hylids and frogs of the genus *Eleutherodactylus* and with bolitoglossine salamanders, the two other large taxonomic and geographic segments of the Middle American amphibian fauna.

There is also a chapter on conservation, keys to adults, and a table of larval characteristics. Results of phylogenetic analyses are provided for most hypothesized lineages. As in the original edition, there are extensive tables showing the distribution of species within ecogeographic regions; altitudinal distribution, habitat, and reproductive sites; and an appendix listing all newly acquired museum specimens.

WILLIAM E. DUELLMAN is Curator Emeritus in the Natural History Museum and Professor Emeritus in the Department of Ecology and Evolutionary Biology at The University of Kansas. He has conducted active field work in the neotropics continuously since 1951. Professor Duellman is the author of numerous papers and monographs on Middle American and South American amphibians and reptiles and the author of several books, most recently of *Biology of Amphibians*, co-authored with Linda Trueb in 1985 (new printing in 1994) and *Patterns of Distribution of Amphibians*, edited by him in 1999.

DAVID M. DENNIS was head of the Biological Illustration Unit of the College of Biological Sciences at The Ohio State University for 30 years but now resides in Sarasota, Florida. He is widely recognized as one of the foremost illustrators of amphibians and reptiles. His award-winning natural history paintings have been displayed in major galleries and exhibits.

Some Newly Described Species of Frogs Illustrated in the Book
Note: These reproductions were made from color slides, but those in the book have been laser-scanned directly from the original watercolors and, therefore, are of a higher quality.

Specifications: 1170 pages, 443 figures including maps, 88 tables, 6 appendices, 92 plates (48 black-and-white, 44 in full color, color frontispiece). Format 8½ by 11 inches (21.5 by 28 cm), clothbound in 2 volumes. ISBN 0–916984–56–7. To be published in July 2001.

PRICES: Pre-publication to SSAR members US$95; Institutions, non-members US$125. ***SHIPPING:*** USA, add US$5; non-USA, US$10.

SEND ORDERS TO: Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, 3507 Laclede Avenue, Saint Louis, Missouri 63103–2010, USA (*telephone:* area code 314, 977–3916 or –1710; *fax:* 314, 977–3658; *e-mail:* ssar@slu.edu). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may also be charged to MasterCard or VISA (please provide the account number and card expiration date). Current SSAR membership information and a complete list of all Society publications can be obtained on request to Dr. Aldridge.

MEETINGS

Meetings Calendar

21–22 April 2001—24th annual All Florida Herpetology Conference, Sheraton Hotel, Gainesville, Florida, USA. Sponsored by Florida Museum of Natural History and Gainesville Herpetological Society. Details from: www.flmnh.ufl.edu/natsci/herpetology/afhc.htm.

5–10 July 2001—American Society of Ichthyologists and Herpetologists, 81st annual meeting, Pennsylvania State University, State College, Pennsylvania, USA. Details from: www.outreach.psu.edu/c&i/ichher/.

14–17 July 2001—International Herpetological Symposium 25th Annual Meeting, Detroit Zoological Institute in Detroit, Michigan, USA. *Refer to meeting announcement above for details.*

13–17 July 2001—Societas Europaea Herpetologica 11th General Meeting, Slovenia. Details from: DPPVN/DAPTF Slovenia, Ptujska c. 91, SI-2327 Race, Slovenia; fax: +386 (0)2 788 30 51; e-mail: milan.vogrin@guest.arnes.si.

27–31 July 2001—44th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League (http://www.inhs.uiuc.edu/cbd/HL/HL.html). Indiana University/Purdue University, Indianopolis, Indiana, USA. Details available on page 1 of this issue of *HR* and on the SSAR web site: www.ukans.edu/~ssar/an-mtng.html.

19–23 September 2001—Association of Reptilian and Amphibian Veterinarians, Eighth Annual Conference, Orlando, Florida, USA. Details from: Charles J. Innis, VMD, VCA Westboro Animal Hospital, 155 Turnpike Road, Westboro, Massachusetts 01581, USA; tel. 508-366-1444; fax 508-634-6997; e-mail: clemmys@aol.com.

2–9 December 2001 (note change of dates)—Fourth World Congress of Herpetology, Colombo, Sri Lanka. Details from: 4WCH Promotions Office, 95 Cotta Road, Colomba 8, Sri Lanka; e-mail: admin@4wch.com; http://www.4wch.com.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Jennifer Garrison** or **Eli Greenbaum**; postal and email addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Evolution of Ranid Frogs in Madagascar and Asia

The highly conserved body plan of anurans has hindered efforts to demonstrate convergence among ecologically specialized species of frogs. Bossuyt and Milinkovitch sequenced mitochondrial and nuclear DNA sequences of all Madagascan and Asian subfamilies of Ranidae (with the exception of the African subfamily Ptychadeninae) to produce the first phylogenetic hypothesis for this group. Data were analyzed with PAUP*; both maximum parsimony and maximum likelihood analyses were performed. A monophyletic origin for Madagascan ranids is supported by the data. However, monophyly of the genus *Limnonectes* and the subfamilies Rhacophorinae, Tomopterninae, and Ranixalinae is not supported by the data. The authors discuss convergence of larval and adult ecomorphs among Madagascan and Asian ranids and suggest that the relationships of these frogs can be understood within the context of plate tectonics.

Bossuyt, F., and C. Milinkovitch. 2000. Convergent adaptive radiations in Madagascan and Asian ranid frogs reveal covariation between larval and adult traits. Proceedings of the National Academy of Sciences 97:6585–6590.

Embryological Development of the Turtle, *Carettochelys insculpta*

Standard series of embryological stages are essential for the comparison of embryos incubated under differing conditions and to facilitate comparisons between and among taxa. The authors staged embryos of the turtle *Carettochelys insculpta* and noted differences between the development of this species and that of *Chelydra serpentina* (Stages 12–26). Non-destructive characters useful for staging (e.g., development of the extra-embryonic vitelline circulation) were observed by candling and described within the framework of a 26 stage series. Opaque patch attributes were useful before stage 5, embryo attributes and measurements were used between stages 5–22, and proportion of yolk mass inside the egg was used to estimate stages 23–26. This study will allow future workers to estimate the age of developing embryos without damaging the eggs of this highly threatened species.

Beggs, K., J. Young, A. Georges, and P. West. 2000. Ageing the eggs and embryos of the pig-nosed turtle, *Carettochelys insculpta* (Chelonia: Carettochelydidae), from northern Australia. Canadian Journal of Zoology 78:373–392.

Olfactory System Histochemistry in the Agamid, *Physignathus lesuerii*

The olfactory system of most terrestrial vertebrates consists of two parts—the olfactory mucosa (receptor cells connect to the main olfactory bulb) and the vomeronasal organ (also known as Jacobson's organ; receptor cells connect to the accessory olfactory bulb). Lectin binding histochemistry was used to elucidate the cell-surface glycoconjugates of both components of the olfactory system in the Australian agamid, *Physignathus lesueurii*. Results of these experiments suggest that the receptor cells of the olfactory and vomeronasal organs contain D-acetylglucosamine and a-D-galactose terminal residues. These residues may be integral to olfaction and could be used to study specific odorant receptors. Previous workers have suggested that glycoconjugates may be important components in olfactory system development and regeneration.

Franceschini, V., M. Lazzari, and F. Ciani. 2001. Lectin-binding patterns in the olfactory system of the lizard, *Physignathus lesueurii*. Journal of Morphology 247:34–38.

Anatomy of Venom Expulsion in *Crotalus*

The intraglandular pressure hypothesis states that the m. pterygoides glandulae assists in venom expulsion. The authors tested this hypothesis and investigated functional subdivisions within the extrinsic musculature of the venom gland in rattlesnakes of the genus *Crotalus*. Venom glands and extrinsic musculature were examined in histological sections and via clearing and staining with Sudan Black B. Venom expulsion pressure was measured with a PT300 pressure transducer and a bipolar stimulating tube was used to stimulate muscles. Anatomy and spatial relationships of the m. pterygoides glandulae and m. compressor glandulae are discussed. Venom expulsion pressure (flow) was greatest when the m. compressor glandulae was stimulated on the medial side; stimulation of the muscle on the dorsolateral side yielded the least amount of venom. Stimulation of the m. pterygoides glandulae resulted in more venom flow than the m. compressor glandulae regardless of the side stimulated. The two muscles have different functional roles and produce force vectors that are nearly opposite. The results suggest that the m. compressor glandulae may have several functionally independent muscle compartments, whereas the m. pterygoides glandulae does not. The authors suggest other unidentified factors may contribute to regulation of venom flow.

Young, B. A., K. Zahn, M. Blair, and J. Lalor. 2000. Functional subdivision of the venom gland musculature and the regulation of venom expulsion in rattlesnakes. Journal of Morphology 246:249–259.

Aquatic Funnel Traps Estimate Population Size in *Taricha granulosa*

Aquatic funnel traps may prove useful in estimating and monitoring population size of amphibians in lentic habitats. The authors tested the ability of aquatic funnel traps to capture a constant proportion of a population of *Taricha granulosa* in different densities and whether biases in sampling resulted from the presence of female newts in traps. Data indicated that the number of newts captured increased with population density, and the presence of females in traps increased the number of newts captured. Thus, future workers will need to consider this bias when using aquatic funnel traps in population studies.

Wilson, C. R., and P. B. Pearman. 2000. Sampling characteristics of aquatic funnel traps for monitoring populations of adult rough-skinned newts (*Taricha granulosa*) in lentic habitats. Northwestern Naturalist 81:31–34.

Molecular Phylogeny of North American Softshells

Few molecular phylogenetic studies have examined widely distributed taxa in North America. The authors studied the genetic structure of three species of the trionychid genus *Apalone*, a widely-distributed and relatively old taxon. Cytochrome B sequences were obtained from 49 turtles in 35 localities and aligned sequences were analyzed with phylogenetic parsimony and neighbor-joining in PAUP*. Results indicated that *A. ferox* has a low amount of genetic variability and may represent an isolated population from the Pliocene. Genetic variability was high in *A. mutica* and *A. spinifera*; the authors suggest these species shared a vicariant event during the Pliocene or Pleistocene. Reduced genetic variation in northern populations suggests a recent migration into formerly glaciated areas. Although most North American turtles are noted for their slow rate of molecular evolution, the results of this study suggest that *Apalone* has a high rate for reasons that are not clear.

Weisrock, D. W., and F. J. Janzen. 2000. Comparative molecular phylogeography of North American softshell turtles (*Apalone*): Implications for regional and wide-scale historical evolutionary forces. Molecular Phylogenetics and Evolution 14:152–164.

Residency, not Physical Attributes, Predicts Winner in Male-Male Skink Contests

The authors studied Tasmanian snow skinks, *Niveoscincus microlepidotus*, in their natural habitat to determine what factors most influenced the outcome of agonistic interactions between males. This species is not strictly territorial, and some males wan-

der into the overlapping home ranges of other males while searching for prey and mates, resulting in combat. Snow skinks are known to hibernate, and most combat occurs soon after the lizards emerge from hibernacula. Observations of a population were made over a five-year period on the island of Tasmania at 1270 m elevation. Thirty-two interactions were monitored, and all but one of the 49 males were captured and measured for various morphological traits. No consistent difference in SVL or mass/length ratio was measured between "winners" and "losers." However, ownership, or residency, was strongly correlated with success (71.9% of winners were residents).

OLSSON, M., AND R. SHINE. 2000. Ownership influences the outcome of male-male contests in the scincid lizard, *Niveoscincus microlepidotus*. Behavioral Ecology 11:587–590.

Regulating Factors Affecting the Loss of External Gills in Red-eyed Tree Frogs

Experiments were conducted using embryos and tadpoles of *Agalychnis callidryas* to determine the effect of oxygen availability on the timing of gill regression. The effects of age at hatching on gill regression were also studied. This species oviposits arboreally, with tadpoles falling into water after hatching. The author found that there was a correlation between gill loss and age at hatching. Cessation of gill circulation was more rapidly accomplished in older embryos (7 days) than in younger embryos (5 days). The amount of egg surface that was exposed to the air had an effect on both gill filament length and circulation. When more egg surface was exposed to air, circulation in external gills ceased by day 7, and gill length was significantly shorter than that observed for "low-exposure" embryos. Those individuals in the low-exposure treatment maintained full gill circulation through day 7. Finally, the author's results show that exposure to hypoxic versus normoxic water also influences gill length and perfusion. In general, gill loss is rapid in *Agalychnis callidryas*—gills that are 60% of the body length and fully perfused at hatching can be bloodless within 5 minutes and completely adducted within 2 hours.

WARKENTIN, K. 2000. Environmental and developmental effects on external gill loss in the red-eyed tree frog, *Agalychnis callidryas*. Physiological and Biochemical Zoology 73:557–565.

Phylogeny and Unisexuality of Caucasian Rock Lizards

The authors conducted a molecular study to determine the relationships among Caucasian rock lizards. Allozyme data were used to analyze parentage of 7 unisexual species, define species boundaries, and reconstruct phylogeny. mtDNA sequence data were used to identify parentage and reconstruct the overall phylogeny (including 15 bisexual species) of the genus *Darevskia*. All analyses were perfomed using PAUP* and the outgroups for DNA analysis were *Algyroides fitzingeri, Lacerta media, L. monticola,* and *L. vivipara*. Of the 2851 base pairs of mtDNA sequence data, 769 were found to be potentially cladistically informative. Analysis resulted in a single most parsimonious tree with strong resolution and support. Investigation of 35 allozyme loci yielded 18 informative characters. Analysis of allozyme data resulted in 89 equally parsimonious trees. A consensus tree of both data sets and the hypothesized parentage of the unisexual species is provided. Hybridization leading to unisexuals was found between only two clades (never within clades), and was found to be directional, with certain clades providing only maternal and others only paternal parents. It is hypothesized that certain clades do not contribute to unisexual production because of phylogenetic, genetic, and possibly ecological constraints.

MURPHY, R., J. FU, R. MACCULLOCH, I. DAREVSKY, AND L. KUPRIYANOVA. 2000. A fine line between sex and unisexuality: the phylogenetic constraints on parthenogenesis in lacertid lizards. Zoological Journal of the Linnean Society 130:527–549.

Review of Contaminant Effects on Lizard Species

This paper represents an extensive review of available literature regarding organic and inorganic contaminants and their effects on lizard species. Lizard species, while an important part of many ecosystems (e.g. biomass and ecological roles), are often omitted from environmental impact studies. In an attempt to stress the importance of including this type of data when creating realistic ecological models, and to encourage further studies, the authors have summarized data regarding residue, bioaccumulation, and lethal effects of organic, inorganic and radionuclides/radiation contamination on lizard species. Twenty-six families and over three dozen contaminants (organic/inorganic) are included in the extensive tables. Also included are the localities and time periods over which the summarized studies were produced. This study not only encapsulates what is known regarding contaminant effects on lizard species, it also points out where information gaps exist.

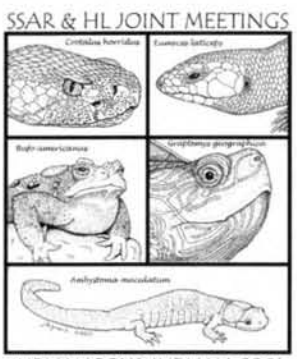
Phenotypic Plasticity and Treefrogs: Testing Responses to Pond Drying



It is often assumed that larval anurans that utilize temporary breeding ponds, once past a critical developmental stage, can respond adaptively to drying habitat by increasing the rate of development towards metamorphosis. The authors investigate this assumption using a 6x6 experimental design and two treefrog species. Adults of the species *Hyla cinerea* most often use permanent bodies of water for breeding, while *H. gratiosa* breed in temporary ponds. It was hypothesized that if a species that often used more ephemeral pools was subject to drying it would be capable of metamorphosing sooner than a conspecific exposed to constant water levels. In addition, permanent pond breeders were predicted to lack the phenotypic plasticity to respond in this way to drying because these species experience little selection pressure from drying. The results of this study show that higher levels of effective density produced longer larval periods and a smaller size at metamorphosis. However, neither species increased its rate of development in response to drying of the pond (as compared with the constant-environment control animals). Several theories regarding primary causative agents for these results are discussed.

Hubert Saint-Girons, 1964.

Hubert Saint-Girons passed away after a short illness on 18 April 2000 in Nantes, not far from his home at Bohallard, close to the small town of Nozay in the west of France. A born naturalist, talented histologist, student of population dynamics, and France's most noted herpetologist, he made an enormous contribution to French science over a period of more than fifty years, starting in 1946. He received his doctorate in 1951, at the University of Paris—the subject being the reproductive biology and ecology of European vipers. This laid the groundwork for his life-long interest in snakes, which he studied with such passion in the grounds of his small château at Bohallard.

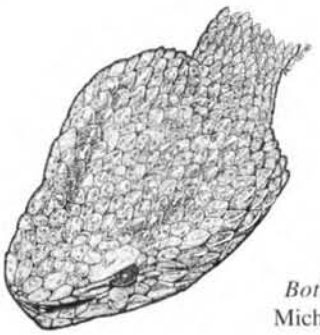
As Directeur de Recherche au CNRS he worked for many years at the Centre d'Ecologie at Brunoy, before moving to his base laboratory at the Université Pierre et Marie Curie in the Laboratoire d'Evolution des Etres Organisés in Boulevard Raspail in Paris. From there he carried out all his detailed histological studies during six months of the year—the other six months being devoted to field work at Bohallard.

One of the notable aspects of his distinguished career was his ability to change from one field to another, mastering each new discipline in its turn. His early studies were done in collaboration with Manfred Gabe—perhaps one of the world's finest histologists—and he inherited many of the exquisite skills that he em-

ployed in his morphological research directly from Gabe, who unfortunately passed them to no other. Hubert was also one of the first zoologists to attempt to correlate laboratory with field studies of animals in their natural environment and this led to his interest in, and contribution to, the new field of ecophysiology. His pioneering work on the sources of energy and materials stored by animals prior to reproduction, which he published in the 50s, predates by many years the now highly fashionable field of 'income' versus 'capital breeders.' He also made a major contribution to studies of hibernation in mammals, again combining field and histological studies to unravel the nature of the basic mechanisms involved.

Even a brief look at only a few of Hubert's papers quickly allows one to see that he not only published in a range of disciplines, but he also varied the approach he took to his work. His studies of snakes are especially noteworthy for encompassing both field and laboratory and for pioneering the use of outdoor enclosures as a useful adjunct. Large enclosures allowed Hubert to maintain and study snakes in relatively controlled, but semi-natural, conditions. Many of the observations that he made on snakes in enclosures have produced important conclusions, as well as hypotheses that now can be tested, using newer techniques, on free-ranging animals in the field. Hubert himself, however, was not a heavy user of "high-tech" methods such as radiotelemetry. Instead, he relied on his skills as a naturalist to locate marked animals in the field and draw his conclusions. This is evident even in his most recent field studies from the 1990s.

Hubert's pioneering contributions spanned not only a diversity of taxa, concepts, and methods, but also involved a remarkably broad set of environments. Although his beloved vipers were the centerpiece of his work, he also conducted some of the first rigorous studies of the ecology and reproductive biology of tropical reptiles. In a field that is still dominated by studies of northern temperate-zone species, his research on the snakes of Cambodia and New Caledonia deserve special mention. He worked extensively in the High Atlas of Morocco, collecting and describing new species, among them *Vipera latastei monticola* (now *V. monticola*). One might also cite the major monographs (published with Gabe) on the histology of the rare New Zealand tuatara (*Sphenodon punctatus*) and the detailed cytology of the nasal cavity and Jacobson's Organ of many reptiles.



He participated in many important field trips in far-flung parts of the world. One memorable trip to the desert of northwest Australia in 1978 (with other herpetological luminaries such as Carl Gans and Hal Cogger) went well until a wheel on the laboratory-caravan exploded some 200 km from the nearest town! Most of the team were left by the side of the road while the more mechanically minded headed off with the salvaged pieces in search of an expert welder. It was very hot (45°C!) and dusty, and everyone except Hubert became progressively more dishevelled and dirty as time went by. Hubert remained impeccable. Not a speck of dust ever adhered to him! All he ever asked for was a glass of cold white wine at sunset which he drank whilst looking disparagingly at his rather grubby field companions.

Unlike many scientists, Hubert was able to admit when subsequent research showed that he had been wrong in his earlier conclusions. In some early work he, along with many other histologists, misidentified the reptilian corticotroph as a pituitary cell secreting luteinizing hormone instead of adrenocorticotrophic hormone, but corrected this error in a paper published many years later. His work on the cellular structure and secretory capacity of the pituitary gland of reptiles laid the groundwork for later experimental studies by other scientists.

Hubert's work was meticulous and he had evolved a most extraordinary tiny form of shorthand writing that was totally incomprehensible (and indeed, almost invisible!) to others. When correcting the work of other scientists he was positive in his criticisms, suggesting ways of resolving problems and detailing possible future avenues of research. He did not take on students personally but he was always generous with his time and his ideas. Hubert was instrumental in launching the career of many young herpetologists, and not only in France. He was one of the examiners for Rick Shine's PhD thesis in Australia, and doubtless played the same role for others.

He was also an extraordinary host. Legions of foreign scientists have spent some of their best days at Bohallard with Hubert and his gracious wife, Marie-Charlotte, where one became mesmerized by the precision of their wonderful shared life. Marie-Charlotte was also a scientist in her own right (although she insisted that she was a geographer and not a zoologist!) and they shared a unique partnership, starting with their classic paper in *Vie et Milieu* in 1956 on reptilian thermoregulation and continuing with many other papers and translations of books into French over the years. Unfortunately, Marie-Charlotte died a few years before Hubert and his last years were never the same without her.

It is impossible to do justice to Hubert's scientific *œuvre* —he published more than 200 papers, and these are spread over a very wide range of fields. He was, without question, France's most distinguished herpetologist and one acknowledged throughout the world. His greatest regret was not being able to speak English fluently, although he read it with ease. He was, without doubt, a complex personality—witty, charming, and intelligent, an excellent chess player, and a fascinating raconteur capable of dropping penetrating observations on the behavior of others into the conversation when the occasion dictated! We will remember him most for the generosity of his nature. In the English-speaking world, he was not as well recognized as he should have been because most of his papers were published in French and in generally less–well-known journals. Nonetheless, he was almost certainly better appreciated abroad than at home, but this is often the case with exceptional people who do not fit easily into one of the conventional categories. France has lost one of its leading scientists and, seeing the way in which studies in herpetology are discouraged today in that country, we doubt that there will ever be another to replace him.

On the First Report of *Ramphotyphlops braminus* from Egypt: How Many Times Can a Flower-pot Snake be Run Over for the First Time?

SHERIF M. BAHA EL DIN
3 Abdala El Katib Street, Dokki, Cairo, Egypt
e-mail: baha@internetegypt.com

In a recent Geographic Distribution note, Wallach (1999) reported what he described as the first country record of *Ramphotyphlops braminus* for Egypt and Africa north of the Sahara. This statement is inaccurate; two other workers had reported the presence of the species from the country beforehand: Baha El Din (1996) and Saleh (1997). It is understandable that these publications did not reach the attention of Wallach, given their rather restricted circulation and limited availability. However, what prompted me to write this letter are the location and circumstances under which the specimen Wallach reported was collected. MVZ 230077 was found as a bicycle casualty in the Cairo suburb of Maadi. Amazingly, the specimen I reported as the first record for Egypt (SMB 212, in my personal collection) was found in the same suburb and it was a traffic casualty as well (Baha El Din 1996). I could not ascertain what kind of vehicle might have killed it, but given the light damage inflicted on the specimen I would not be surprised if it was a bicycle too! *Ramphotyphlops braminus* appears to be well established in the greater Cairo region and probably large areas of the Nile Valley. The earliest specimen seems to have been collected in 1984 from Cairo, but only identified recently (Saleh 1997).

Artwork & Slides Wanted for *HR*

We are interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor.

Also, we are interested in evaluating outstanding color slides of amphibians and reptiles for possible use on future *HR* covers. If you would like your work to be considered, please contact the Editor ***prior*** to sending any slides. Postal and e-mail addresses are listed on the inside front cover.

Postural Thermoregulatory Behavior in the Nocturnal Lizards *Christinus marmoratus* and *Nephrurus milii* (Gekkonidae)

MICHAEL KEARNEY*
Department of Biological Sciences, Monash University
Clayton, Victoria 3168, Australia

**Present address: School of Biological Sciences, University of Sydney*
NSW 2006, Australia
e-mail: mkearney@bio.usyd.edu.au

The body temperature of a reptile can influence its ability to perform a variety of activities that affect individual survivorship, growth rate and reproductive success (e.g., sprinting, digestion, social interactions). Thus, temperature regulation may increase a reptile's fitness (Huey 1982). Although reptiles are ectothermic and have only limited physiological scope for controlling body temperature (Stevenson 1985), many reptiles are able to maintain their body temperature within certain limits by behaviorally exploiting spatial and temporal variation in their thermal environment (e.g., Cowles and Bogert 1944).

Diurnal reptiles are well known for their ability to thermoregulate behaviorally, but comparatively little is known about this phenomenon in nocturnal species (reviewed in Huey 1982). Because opportunities for behavioral temperature regulation are restricted at night due to the absence of solar radiation, many nocturnal reptiles forage at low and variable body temperatures (Cowles and Bogert 1944; Pianka and Pianka 1976; Pianka and Huey 1978; Autumn et al. 1994). However, the thermal environments within the daytime retreat sites used by reptiles can offer a wide range of potential body temperatures (Huey et al. 1989a; Webb and Shine 1998a) and there is evidence that some nocturnal reptiles do thermoregulate during the day while sequestered within retreat sites (Bustard 1967; Dial 1978; Kearney and Predavec 2000; Schlesinger and Shine 1994; Webb and Shine 1998b; Werner and Whitaker 1978). For instance, in captivity the nocturnal rock-dwelling gecko *Coleonyx brevis* was observed to raise its body from a cool substrate and into contact with a warm overlying rock to gain heat by conduction (Dial 1978).

In this study, I investigated the thermoregulatory behavior of two species of nocturnal Australian lizards, the marbled gecko *Christinus marmoratus* and the thick-tailed gecko *Nephrurus milii*. Field-active marbled geckos have been demonstrated to regulate their body temperature during the day by choosing a thermally suitable retreat site and then by adjusting their position, and possibly also their posture, within the retreat site (Kearney and Predavec 2000). The behavioral mechanisms by which marbled geckos thermoregulate, however, have not been directly observed. Herein, I report direct laboratory observation of postural thermoregulatory behavior in the marbled gecko and the thick-tailed gecko.

Marbled geckos and thick-tailed geckos were collected from a granite outcrop in central Victoria, Australia (36°27'42"S,

143°45'10"E), where they occur in sympatry and shelter beneath rocks (see Kearney and Predavec 2000 for details of the study site). Marbled geckos are small (adult snout–vent length ≈ 50 mm, adult body mass ≈ 2.5 g), arboreal lizards whereas thick-tailed geckos are larger, terrestrial lizards (adult snout–vent length ≈ 80 mm, adult body mass ≈ 10 g). Four marbled geckos (all adults) and four thick-tailed geckos (two adults and two juveniles) were collected in October 1998. Four additional thick-tailed geckos (two adults and two juveniles) were collected in January 1999. There were even numbers of each sex in adult groups and the sex of juvenile geckos was not determined. Geckos were immediately transported to holding facilities at Monash University and maintained under standard conditions (for more details on gecko husbandry, see Kearney and Predavec 2000).

I used an enclosure to observe thermoregulatory behaviors. It consisted of a glass aquarium (600 x 300 x 300 mm) containing an artificial crevice within which geckos could be readily observed through the aquarium wall. The crevice was composed of two slabs of quarried granite (each 295 x 130 x 15 mm) placed side-by-side and elevated above the floor of the aquarium by blocks of wood. A crevice width of 12 mm was used for marbled geckos and juvenile thick-tailed geckos, and a crevice width of 16 mm was used for adult thick-tailed geckos (these dimensions allowed sufficient room for the geckos to raise their bodies above the crevice substrate and still reach the overlying rock). Temperatures within the crevice were monitored with type-T thermocouples that were taped to the undersides of the slabs and to the crevice substrate. A desk lamp, fitted with a dimmer and a clear 25-W globe, was directed onto one of the granite slabs and heated its underside to a maximum temperature of 32°C. The temperature of the underside of the other, adjacent granite slab did not rise above 17°C, thus providing two thermally distinct regions within the crevice. The aquarium was placed on top of an open, portable fridge which cooled the substrate of the crevice to a minimum temperature of 10°C. The entire enclosure was placed in a constant temperature room set at 17°C with a L:D 14:10 photoperiod. The heat lamp was automatically turned on during the light phase of the photocycle.

Between 19 December 1998 and 6 January 1999, geckos were introduced separately to the enclosure and given 24 hours to become accustomed to the new surroundings. Their behavior was then monitored using a Sony TRV99E video camera from behind a black screen. After a gecko was observed in an erect posture (see below) for at least one hour, it was removed from the enclosure and its rectal temperature was immediately recorded with a type-T thermocouple thermometer and probe. All geckos were returned to the study site upon completion of the experiment.

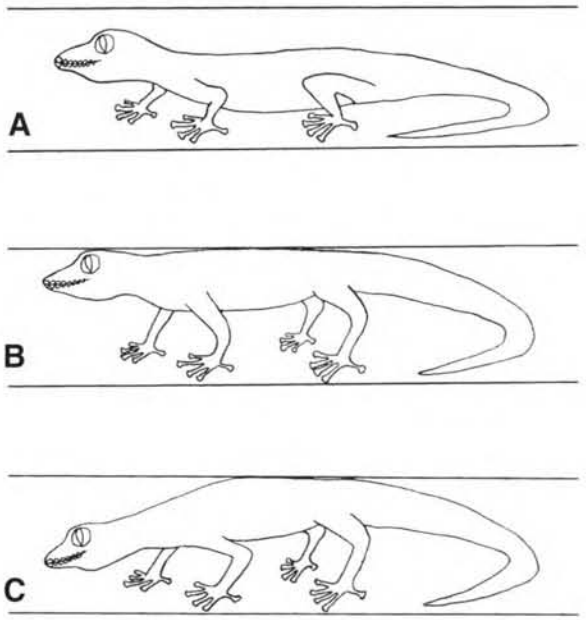

FIG. 1. Thermoregulatory postures assumed by the marbled gecko *Christinus marmoratus* when sequestered in a rocky crevice: (A) resting posture, (B) fully erect posture, (C) semi erect posture. Similar postures were also observed for the thick-tailed gecko *Nephrurus milii*.

When placed in the enclosure, all geckos entered the crevice and assumed an erect posture whereby the body was elevated off the substrate until the dorsal surface contacted the underside of the rock slab (Fig. 1). This posture was very similar to that illustrated for *Coleonyx brevis* in Dial (1978) except that neither marbled geckos nor thick-tailed geckos raised their tails to contact the rock slab. Each of the 12 geckos tested positioned itself

TABLE 2. Mean body temperatures selected by the study species in laboratory thermal gradients and in the present study.

Species	Mean	SD	N	Testing apparatus (range °C)	Reference
Christinus	27.6	0.42	3	Photothermal gradient (25–70)	(Licht et al. 1966)
marmoratus	27.1	0.81	3	Substrate gradient (25–70)	(Licht et al. 1966)
	27.3	0.83	8	Substrate gradient (12–45)	(Daniels 1984)
	27.7	1.33	5	Substrate gradient (5–45)	(Angilletta and Werner 1998)
	24.3	2.11	30	Substrate gradient (11–45)	Kearney, unpubl.
	25.9	0.56	4	Artificial crevice (10–32)	This study
Nephrurus milii	27.3	—	5	Photothermal gradient (25–70)	(Licht et al. 1966)
	21.6	—	12	Substrate gradient (15–30)	(Licht et al. 1966)
	24.2	2.96	4	Artificial crevice (10–32)	This study (adults)
	26.3	1.34	4	Artificial crevice (10–32)	This study (juveniles)

beneath the rock slab that was in direct contact with the heat source before assuming the erect posture. This is very unlikely to have occurred by chance ($\chi^2 = 12$, $df = 1$, $P < 0.001$) and further suggests that this posture plays a thermoregulatory role. There is also indirect evidence that marbled geckos within retreat-sites in the field use such postural thermoregulatory adjustments during the day (Kearney and Predavec 2000). Occasionally, prior to assuming the erect posture, marbled geckos were observed to repeatedly contact the underside of the rock slab with their snout. The density of skin sensory receptors in geckos is highest on the anterior part of the head (Matveyeva and Ananjeva 1995) and this tactile behavior may enable the geckos to choose a thermally suitable position before assuming the erect posture. Snout contact with the rock underside was not observed in thick-tailed geckos.

In addition to raising and lowering the entire body when thermoregulating (cf. *Coleonyx brevis* [Dial 1978]), both species in this study may have used subtle adjustments of the amount of body surface in contact with the rock slab in order to regulate body temperature. Frequently, the geckos would lower their head out of contact with the rock and remain in an arched position for a number of minutes, and then raise their head back into contact with the rock (Fig. 1B & C). The erect posture was typically maintained for periods of at least an hour, with one thick-tailed gecko remaining in this posture for over 5 hours.

The body temperatures of geckos in the erect posture were much higher than the substrate temperature (circa 10°C) and were broadly similar to published values of body temperatures selected in laboratory thermal gradients (Tables 1 and 2). Variation in the mean selected body temperature of the marbled gecko appears to be lower in this study than in other thermal gradient studies (Table 2) suggesting that this may be a useful alternative method of measuring the preferred body temperature of lizards that exhibit distinct postural thermoregulatory behaviors. In contrast, variation in the mean selected body temperature of thick-tailed geckos was large relative to the marbled gecko (Table 2), although this may reflect a seasonal shift in preferred body temperature since all four geckos collected in summer selected higher body temperatures than those collected in spring ($N = 8$, $t = -3.492$, $P = 0.031$; Table 1).

Temperature differentials between the substrate and the "ceiling" of rocky retreat-sites in the field are commonly around 5 to 10°C and can reach as much as 20°C (Webb and Shine 1998a; personal observation). Thus, the erect posture described in this report would be of great thermoregulatory utility to a rock-dwelling gecko, and perhaps also to lizards using other types of retreat-sites such as burrows. However, the same posture appears to be used by geckos in a variety of other situations. For instance, the thick-tailed gecko (personal observation), and at least 11 other species of gecko (Greene 1988) elevate their bodies in a similar manner when confronting potential predators. Similar postures may also be used by foraging geckos to extend their field of view (Werner and Broza 1969). Whether such behaviors were the evolutionary precursors for the thermoregulatory behavior or were secondary applications is unknown.

Although nocturnal lizards are capable of activity at relatively low temperatures, my observations add to the evidence that these lizards possess adaptations to behaviorally maintain high and constant body temperatures during the daytime (Autumn et al. 1994; Bustard 1967; Dial 1978; Kearney and Predavec 2000; Schlesinger and Shine 1994; Werner and Whitaker 1978). Such behavior may be critical in enabling nocturnal lizards to successfully perform many physiological functions, in light of the similarity in thermal preferences, tolerances and sensitivity of performance between nocturnal and diurnal lizards (Autumn et al. 1994; Autumn and De Nardo 1995; Avery 1982; Huey et al. 1989b; Werner and Whitaker 1978). Studies of other nocturnal taxa may reveal additional diversity in the thermoregulatory behavior of reptiles.

TABLE 1. Body temperatures (°C) of geckos in thermoregulatory postures.

Christinus marmoratus (adult)	*Nephrurus milii* (adult)	*Nephrurus milii* (juvenile)
25.1	21.8	25.1
26.3	21.5	25.2
26.2	27.1*	27.0*
26.1	26.4*	27.8*

*Collected in summer (all other individuals collected in spring).

Acknowledgments.—I thank M. Predavec for providing laboratory facilities and useful advice, and S. Downes, M. Predavec, and R. Shine for comments on the manuscript. This project was approved by the Animal Care and Ethics Committee at Monash University, and conducted under Research Permit RP-97-097 issued by the Department of Environment and Natural Resources, Victoria, Australia.

Attempts to Estimate the Original Size of Partly Digested Prey Recovered from Stomachs of Japanese Anurans

TOSHIAKI HIRAI
and
MASAFUMI MATSUI
Graduate School of Human and Environmental Studies
Kyoto University, Sakyo-ku, Kyoto 606-8501, Japan
e-mail (MM): fumi@zoo.zool.kyoto-u.ac.jp

In most studies of anuran food habits, the number of prey ingested, and less frequently the size in length of prey, have been taken as numerical traits. However, volume or weight of prey are more suitable parameters of prey size for analytical studies such as relative energetic contributions of each prey taxon. The regression formulas between body length and wet weight calculated for some arthropod taxa (Zug and Zug 1979), or for combined arthropods (Rogers et al. 1976, 1977) enabled us to estimate weight of food from its length. However, food items extracted from digestive tracts are usually broken into fragments by digestion, and this makes it difficult to measure the original size of prey itmes, which is necessary for estimating their volume or weight. In this paper, we present regression analysis of body parts that are often undigested or incompletely digested and original total body length for some arthropod prey taxa consumed by several Japanese anuran species.

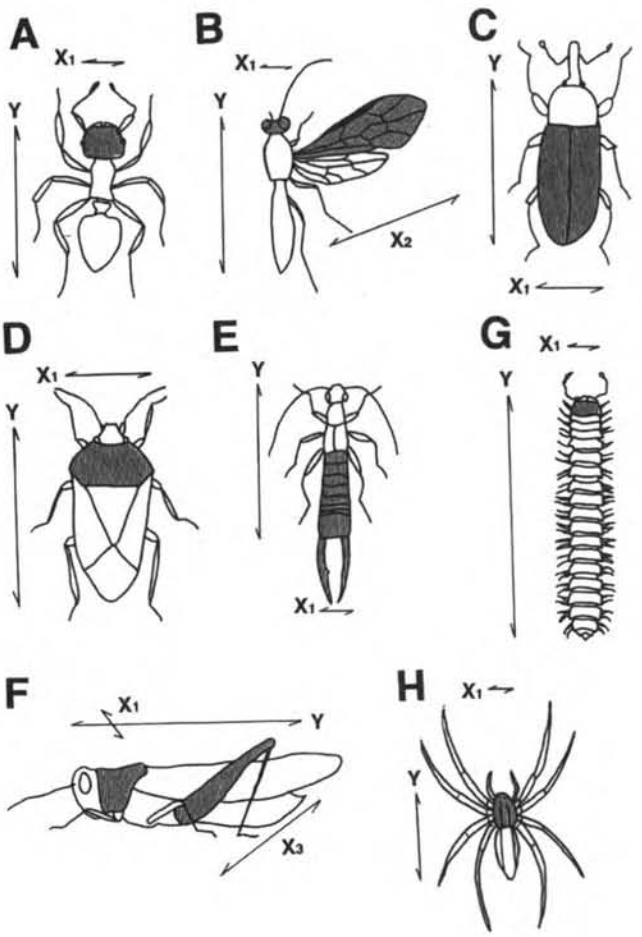

Fig. 1. Measured body parts (Y:body length; X1:width of body part; X2:forewing length; X3:femur length) of representative individuals of types of arthropods taken by frogs. Arrows indicate character dimensions; shaded parts usually remain undigested in frog stomachs. A: ants; B: wasps; C: snout beetles; D: pentatomid bugs; E: earwigs; F: grasshoppers; G: millipedes; H: spiders.

Measurements were made of body parts of prey recovered from stomachs of *Rana nigromaculata*, *R. porosa brevipoda*, *R. rugosa*, and *Hyla japonica* and of those of comparable intact prey animals. Both stomach samples and intact prey animals were collected in rice fields around Kyoto and Otsu, Central Japan. Details about methods of sampling and measurments are given elsewhere (Hirai and Matsui 1999, 2000). Pearson product-moment correlation coefficients (Zar 1999) were calculated between body parts (body width, thigh length, forewing length) and total body length of each prey taxon.

Most of the prey animals extracted from the stomachs were digested and broken into fragments. However, heads of ants and wasps, as well as the abdomens and elytra of beetles, remained intact and their width could be measured (Fig. 1A–C). In the case of crane flies (Tipulidae), fruit flies, moths, pentatomid bugs, water-striders, leafhoppers (deltocephalids), grasshoppers

TABLE 1. Relationships between size of body parts (X in mm) and total body length (Y) of arthropods. X is a corresponding part of body actually measured.

Prey taxa	Formula	X	r^2	N
Ants	Y=4.75X-0.62	X1:Head width	.844	705
Wasps	Y=3.92X+0.73	X1:Head width	.923	39
	Y=1.14X -0.05	X2:Forewing length	.898	23
Larval wasps	Y=5.37X+1.64	X1:Body segment width	.561	52
Ground beetles	Y=2.45X+0.68	X1:Abdomen width	.823	86
Rove beetles	Y=4.57X+0.73	X1:Abdomen width	.810	23
Scarab beetles	Y=1.91X-0.50	X1:Abdomen width	.944	51
Click beetles	Y=3.18X+0.39	X1:Abdomen width	.853	49
Leaf beetles	Y=1.20X+1.96	X1:Abdomen width	.689	32
Snout beetles	Y=2.01X+0.57	X1:Abdomen width	.914	149
Fruit flies	Y=3.57X-0.10	X1:Thorax width	.781	64
	Y=1.08X+0.48	X2:Forewing length	.876	26
Crane flies	Y=5.76X+0.82	X1:Thorax width	.823	160
	Y=0.92X+0.52	X2:Forewing length	.910	52
Moths	Y=2.44X+3.62	X1:Thorax width	.679	44
Caterpillers	Y=4.66X+5.23	X1:Body segment width	.732	272
Pentatomid bugs	Y=1.94X-0.28	X1:Thorax width	.910	51
Reduviid bugs	Y=3.79X-0.17	X1:Abdomen width	.925	13
Water striders	Y=3.58X+2.08	X1:Thorax width	.474	36
Leafhoppers	Y=3.01X+0.32	X1:Thorax width	.935	15
Earwigs	Y=3.66X+3.86	X1:Abdomen width	.814	24
Grasshoppers	Y=7.74X-4.74	X1:Thorax width	.924	28
	Y=1.75X+0.97	X3:Femur length	.943	15
Grouse locusts	Y=3.21X-1.05	X1:Thorax width	.794	30
	Y=2.64X-5.14	X3:Femur length	.856	8
Crickets	Y=3.25X+1.29	X1:Thorax width	.859	11
	Y=1.35X+1.35	X3:Femur length	.943	9
Spiders	Y=2.30X+1.21	X1:Prosoma width	.719	484
Woodlice (Oniscidae)	Y=2.00X+1.38	X1:Body segment width	.870	176
Woodlice (Armadilliidae)	Y=2.06X+0.94	X1:Body segment width	.835	61
Millipedes	Y=9.62X-0.57	X1:Body segment width	.852	64
Centipedes	Y=11.30X-0.86	X1:Body segment width	.863	14

(Locustidae), grouse locusts (Tetrigidae), and crickets (Gryllidae), thoraxes were usually intact (Fig. 1D, F). Abdomens of reduviid bugs and earwigs, and prosoma of spiders were also intact (Fig. 1E, H). We could measure body width of larval wasps, caterpillars, and other arthropods because some body segments usually were partially intact even when other body parts were more digested (Fig. 1G). Forewings of wasps, crane flies, and fruit flies usually remained in the stomach even when the body was absent (Fig. 1B). Similarly, saltatorial legs of orthopterans tended to remain in the stomach, and we could measure their femur length (Fig. 1F).

The regression formulas between body parts (body width, thigh length, forewing length) and total body length are summarized in Table 1. Correlation coefficients obtained were significant for all prey taxa examined, at the level of 0.01%.

Results of this study suggest that we can estimate original body length of digested prey from the size of non- or poorly-digested body parts such as heads of ants, elytra of beetles, and thoraces and thighs of grasshoppers. Food volume can also be calculated from the body length using body width to make the estimate (e.g., Dunham 1983). We can use the estimated value for statistical comparisons of body size and frog gape size (Hirai and Matsui 1999, 2000). The body length estimated in this way will further enable us to calculate food weight using the formulas presented by Zug and Zug (1979) or Rogers et al. (1976, 1977). Hence, these regression formulas are useful to express diet compositions by volume or weight, or eventually to evaluate energetic contributions by each prey taxon.

This study was based on data from diet studies of frogs inhabiting rice fields, but anurans dwelling in different habitats consume different prey taxa. For example, carabid beetles are often taken by *Bufo japonicus*, cave crickets by *Rana tagoi*, and termites by *Microhyla ornata* (Maeda and Matsui 1999). These prey taxa, which we could not include in this study, should be investigated in the future. Furthermore, similar attempts should be made in other geographic regions so as to determine whether or not the present data are applicable to their anuran fauna.

Ultraviolet Reflectance in the Small Skink *Carlia pectoralis*

SIMON P. BLOMBERG*

Many vertebrates have ultraviolet (UV) vision (Jacobs 1992; Tovée 1995). Among lizards, the anoles (family Polychrotidae) are most well-studied in terms of visual communication involving UV light. In *Anolis carolinensis*, the visual pigments have been characterized and one (SWS1[Ac]), has been found to be most sensitive at 358 nm, in the UV region of the spectrum (Kawamura and Yokayama 1998). Evidence for the behavioral use of UV reflectance comes from a study of the dewlaps of five other *Anolis* species (Fleishman et al. 1993). Two species (*A. krugi* and *A. cristellatus*) had highly UV reflectant dewlaps (Absolute reflectance > 35% at 365 nm), while another two species (*A. evermanni* and *A. gundalachi*) had low UV reflectant dewlaps (< 22%). A further species (*A. pulchellus*) was intermediate in dewlap reflectance (25%). Importantly, the species with highly UV reflectant dewlaps live in microhabitats exposed to direct sunlight, while the two low reflectant species live in closed-canopy forest, suggesting a strong link between UV visual communication and environmental light regimes. However, UV sensitivity of photoreceptors only broadly matched the spectral radiance of the habitats, suggesting only a modest amount of coevolution between the dewlap 'signal' and the photoreceptor 'receiver' (Fleishman et al. 1997). Also, the desert iguana (*Dipsosaurus dorsalis*) produces femoral gland secretions that are highly reflectant to UV, and behavioral experiments suggest that that species is visually sensitive to the near UV and can locate UV reflectant markers (Alberts 1989). To our knowledge, UV reflectance and communication has not been reported in any other group of lizards.

The small, leaf-litter dwelling Australian skink, *Carlia pectoralis*, is a member of a genus that exhibits considerable sexual dichromatism (Greer 1989). In this species, breeding males possess orange lateral stripes which attract females and are also used in aggressive contests with other males (Blomberg and Owens, unpubl.). Interestingly, however, breeding males also have a grey-blue gular (throat) region. Because *C. pectoralis* lives in open sunlight and appears to rely heavily on color in social interactions, we hypothesized that the gular region, which is dull in the visual part of the spectrum, may be reflective in the UV.

We measured the UV reflectance of the gular region, midlateral stripe, and brown dorsal region of a breeding male *C. pectoralis* using an S2000 optical spectrometer (Ocean Optics, Dunedin, Florida, USA), with a dual deuterium-tungsten lamp. The deuterium lamp is optimized for wavelengths between 200 and 400 nm, while the tungsten lamp is optimized for wavelengths between 350 and 750 nm. A 'labsphere' certified standard was used as the white standard. All measurements were taken in a darkened room in order to minimize interference from extraneous light sources. Measurements were taken at 45° to the skin, over an area of 3 mm in diameter.

As predicted, the gular region of male *C. pectoralis* is highly reflectant in the ultraviolet region, with a peak at 338 nm, whereas other regions of the body show negligible UV reflectance (Fig. 1). Our results are important for two reasons. Firstly, UV reflectance may be much more prevalent than previously expected, and may not be limited to groups that are thought to rely primarily on vision (UV or visual spectrum) for communication, such as anoles. Our

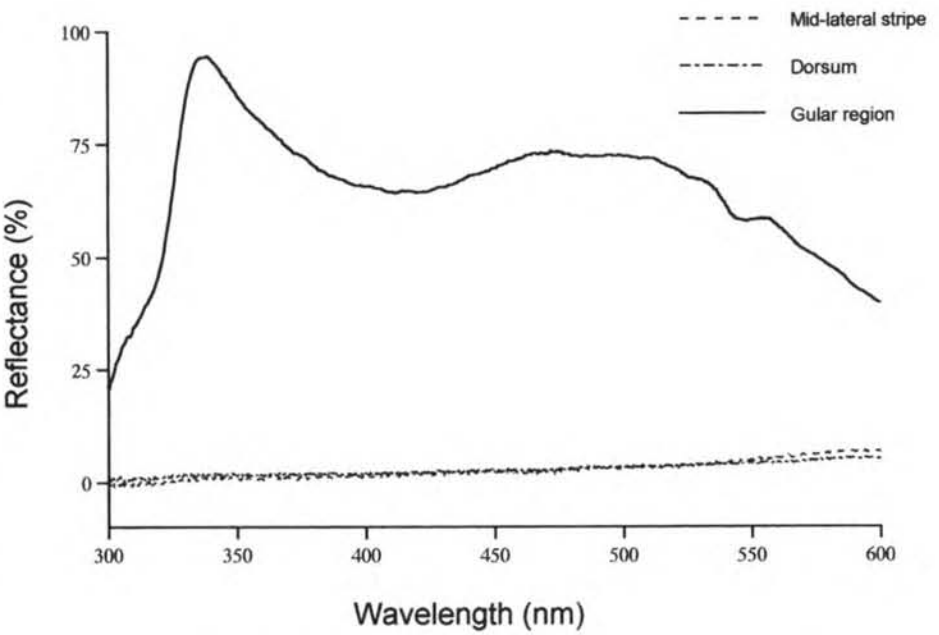

FIG. 1. Ultraviolet reflectance plot for body regions of the small skink, *Carlia pectoralis*.

results suggest that skinks, which are known for their use of chemoreception (e.g., Cooper and Vitt 1984; Cooper and Vitt 1986a, b, c; Nicoletto 1985), can also be highly visually oriented, and may use UV reflectant regions of the body for communication. Secondly, our results suggest that communication in *C. pectoralis* is more complex than previously suspected. Previous studies have concentrated on the adaptive significance of coloration of the orange lateral stripes, which are not UV reflective (Fig. 1; Blomberg and Owens, unpubl.). The role of the gular region in *C. pectoralis* behavior is not known. Casual observation of skinks in the field suggests that it could be related to the "head-nodding" behavior, perhaps as an "amplifier" trait that allows the head nod to be seen over a wider area by flashing in the UV spectrum (Zahavi and Zahavi 1997).

A Clarification of the Type Locality and Collector of the Holotype of *Sauromalus obesus* (Baird) 1858

RICHARD R. MONTANUCCI
Department of Biological Sciences, Clemson University
Clemson, South Carolina 29634-0326, USA
e-mail: rrmnt@clemson.edu

The western chuckwalla, *Sauromalus obesus*, was originally named *Euphryne obesus* by Spencer F. Baird in 1858, and later properly emended to *Euphryne obesa* (Baird 1859). The genus *Euphryne* was eventually synonymized with *Sauromalus* by Cope (1875). In a recent comprehensive study of the genus *Sauromalus*, Hollingsworth (1998) placed *S. obesus* in the synonymy of *S. ater*. As an aside, while I accept the conspecificity of these two nominal taxa, I argue elsewhere (Montanucci 2000) that the name *S. obesus* should be given precedence over *S. ater*.

In Baird's original description (1858:253), the only collection information is the following: "Abundant in the canons of the Colorado, of California, collected by Maj. Thomas, Mex. Boundary Survey, and Lt. Ives' Expedition. Type No. 4172." One might reasonably conclude from Baird's brief statement that the type locality is "canons of the Colorado, of California" and that Major Thomas is the collector. Subsequently, Baird (1859:6) listed USNM 4172 from Fort Yuma without explicitly stating it was the type specimen. He also listed A. Schott as the collector of this specimen, and Major Thomas as the collector of USNM 2774, also from Fort Yuma. Hence, Baird's two published works are incomplete and seemingly contradictory in regards to the type locality and collector of the type specimen (Fig. 1).

***Euphryne obesus*, Baird.**—**Width of head nearly equal to distance from nose to ear. Tail shorter than the body. General color of the young, olive green, with five broad transverse bars above from head to base of tail, and about as many on the tail; these rings yellow, dotted with red. Beneath pea green dotted with black. With increasing age, the bands become obsolete and disappear, the general color becoming reddish olive.**

The largest and heaviest of American *Iguanidæ*, sometimes exceeding a foot in length. Abundant in the canons of the Colorado, of California, collected by Maj. Thomas, Mex. Boundary Survey, and Lt. Ives' Expedition. Type No. 4172

21. EUPHRYNE OBESA, Baird.

PLATE XXVII.

Euphryne obesus, BAIRD, Pr. A. N. Sc. Dec. 1858.

SP. CH.—Width of head nearly equal to distance from nose to ear. Tail shorter than the body. General color of the young, olive green, with five broad transverse bars above from head to base of tail, and about as many on the tail; these rings yellow, dotted with red. Beneath, pea green, dotted with black. With increasing age the bands become obsolete and disappear, the general color becoming reddish olive.

2774 Fort Yuma. Major Thomas.—4172. Do. A. Schott.

FIG. 1. Upper: Description of *Euphryne obesus* from Baird (1858). Lower: Description from Baird (1859). The dash serves to divide the two USNM specimens and their respective collectors. Do. is an abbreviation for "ditto" in reference to the locality. The absence of a period after 2774 is an omission; other numbers on the page are followed by a period. USNM 2774 was erroneously assigned to a chuckwalla specimen; see text for further explanation. Courtesy: David H. Lewis.

In the original ledger at the National Museum of Natural History "Fort Yuma" is given as the locality for USNM 4172. The date of entry is 1858. The names of Major G. H. Thomas and A. Schott appear next to this entry. The name "A. Schott" was penciled into the ledger as the collector after the specimen was catalogued, but when this was done is not exactly known. Thomas is now listed in the computer records as the donor of the specimen. The ledger information is consistent with Baird (1859:6) in indicating that Arthur Schott was the collector of the holotype. Unfortunately, Schott's field journals were not available to me and apparently have been lost (Fontana 1983).

TABLE 1. List of specimens used by Baird (1858) in the description of *Euphryne obesus*.

USNM number	Collector	Locality	Sex	SVL
4172 (holotype)	A. Schott*	Fort Yuma, CA	F	162 mm
11810 (paratype)	H. B. Mollhausen**	Colorado River	M	160 mm
326109(paratype) (previously 11810)	H. B. Mollhausen**	Colorado River	M	95 mm
12264 (paratype)	H. B. Mollhausen**	Yampai Valley, AZ	M	185 mm

* United States and Mexican Boundary Survey (Gadsden Survey; 1854–1855).
** Lieutenant J. C. Ives' Exploring Expedition of the Colorado River (1857–1858).

In neither of Baird's publications is the term "type locality" explicitly used, perhaps because the standards of the time did not require it. In Baird (1858), the word 'habitat,' abbreviated as "Hab.," precedes locality or distribution statements for each species, but it is omitted under the description of *Euphryne obesus*. Multiple localities are listed for some species, while only one is the source of the designated type specimen. Therefore, Baird's statements were apparently not intended as type localities in the modern, strict sense.

Baird's brief, incomplete and contradictory reporting was not without consequences. For example, Stejneger (1891) listed Thomas as the collector of USNM 4172, as did Smith and Taylor (1950), who appended a question mark after his name. Cochran (1961:113) listed both A. Schott and G. G. [*sic*] Thomas as the collectors of USNM 4172 which she designated as a "cotype". Cochran's cotype designation apparently stems from Baird's use of multiple specimens in the original description, although the type specimen is listed. No authors have followed Cochran.

Baird's (1859) listing of USNM 2774 as a chuckwalla is erroneous. W. R. Heyer (pers. comm.) of the USNM informs me that this number is assigned to a specimen of *Holbrookia*. Other permutations of this number were explored, including the most likely, a transposition of the 4 and 2, i.e. USNM 4772. But this museum number is assigned to a *Coluber constrictor*, and no other permutations involve specimens of chuckwallas (R. Crombie, pers. comm.). Cope (1900:267) published a table of chuckwalla specimens examined by Stejneger that includes USNM 4172 as well as others collected by H. B. Mollhausen. On page 268, Cope repeated these numbers, except he listed USNM 4772 as a specimen from Fort Yuma, but since USNM 4172 does not appear in Cope's list, he was probably referring to the type specimen, and 4772 is simply a misprint (it should be noted that, in the old style cursive script, ones and sevens were often very similar). The same misprint had been given earlier by Yarrow (1882), and no other specimen was listed from Fort Yuma (also see De Queiroz 1995:35). Cope may have simply perpetuated Yarrow's mistake. It is possible that a paratopotype collected by G. H. Thomas never existed, otherwise Yarrow (1882) and Stejneger (1891) would likely have listed it. In writing his manuscript on the *Reptiles of the Boundary*, Baird may have listed the Fort Yuma specimen twice: as 4772 collected by Thomas, and as 4172 collected by A. Schott. In preparing the manuscript for publication, the type setter may have then transposed the 2 and 4 in 4772, a possible error, especially because the 2 and 4 flank two identical numbers (i.e. 77). Although speculative, this explanation of how USNM 2774 appeared in Baird's work is supported by the following facts: 1) the names of Arthur Schott and G. H. Thomas are both associated with USNM 4172 in the original ledger, and Thomas' name is linked with 2774 in the 1859 publication; 2) USNM 4172 was misprinted as 4772 in two other papers; 3) the misprinted number 4772 and 2774 have the same integers; and 4) both numbers are associated with the same locality (Fort Yuma).

The chuckwalla specimens that I believe were used by Baird (1858) for the original description are listed in Table 1. These specimens were extracted from the lists of Yarrow (1882), Stejneger (1891), and Cope (1900). No additional specimens catalogued prior to Baird's 1858 paper could be retrieved from the Smithsonian's electronic database, although I did not peruse the original ledger for additional records.

Baird's (1858:253) mention of Major Thomas seemingly ties his name with the United States and Mexican Boundary Survey and also perhaps with Lieutenant Joseph C. Ives' expedition, but apparently this was not his intent. Baird was simply listing the several sources of the preserved material he used for the generic and species descriptions of *Euphryne obesus*. Unfortunately, as constructed, the statement was misconstrued by Yarrow (1875:559) who erroneously associated Thomas with the Boundary Survey. Hollingsworth (1998:40), also linked Thomas with the Boundary Survey, if not also with the exploration of the Colorado River, and credited him with collecting the series of specimens used by Baird. It is clear from historical records, however, that Thomas played no role in either of these expeditions. The career of General George Henry Thomas in the United States Army and his significant contribution to the Union victory in the Civil War are well known (McKinney 1961; Thomas 1964). Drawing upon these two sources, the following relevant information is provided.

In 1854, as a captain, Thomas was reassigned from his duties as an artillery instructor at the United States Military Academy at West Point to take charge of a battalion with the Third Artillery Regiment. He proceeded to Benicia Barracks, near San Francisco, before receiving orders to take command of Fort Yuma, a 333-km overland march from San Diego. Thomas arrived by ship in San Diego and led two companies across the Colorado Desert in the midsummer (July) of 1854, reaching the post with his command in near exhaustion.

Thomas' stay at Fort Yuma was short, barely over a year. In accordance with War Department orders, he and his assistants made

important zoological and botanical collections (McKinney 1961). Thomas was credited as being the first to collect the leaf-nosed bat in U.S. territory, and in other ways adding substantially to the zoological knowledge of the region. While at Fort Yuma, Thomas presumably received the holotype along with other specimens from Schott, and had them shipped to Washington, D. C. Thomas was promoted to the rank of major on May 12, 1855, and ordered to duty with the Second Cavalry Regiment at Jefferson Barracks, Missouri. He left Fort Yuma on July 23, 1855.

Lieutenant Joseph C. Ives led the exploration of the Colorado River that began at the river's mouth on November 28, 1857, more than two years after Thomas left his command at Fort Yuma. Mr. H. B. Mollhausen was a member of the Colorado River expedition and made the zoological collections (Ives 1861). During the exploration of the Colorado River (1857–1858), Major Thomas was in Texas, engaged in military campaigns against the Comanches (McKinney 1961).

FIG. 2. Fort Yuma (note arrow), Imperial Co., California, a view from the Arizona side of the Colorado River showing the scarcity of suitable habitat for chuckwallas. Photo by Carelton Watkins, *circa* April, 1880. Courtesy: Arizona Historical Society, Tucson, Arizona.

William H. Emory, major First Cavalry, was Chief Astronomer for the running of the boundary between United States and Mexico from 1848 to 1853. He was appointed both United States Commissioner and Chief Astronomer in 1854, with full powers, under the Gadsden Treaty, and officially completed the survey in 1857 (Thrapp 1990).

Arthur Schott served as one of the Army surveyors for the Boundary Commission; the following pertinent information is taken from Fox (1977) and Goetzmann (1979). Arthur Carl Victor Schott, born in Germany, emigrated to the United States in 1850, and subsequently befriended Princeton University botanist John Torrey. In 1851, Torrey persuaded Emory to hire Schott as a surveyor and scientific collector. The new Commission to survey the Gadsden Boundary was divided into two parties: one under Emory that was to work its way west from the Rio Grande, and one under Lieutenant Nathaniel Michler that was to proceed via San Diego to the Colorado River, and thence eastward to the 111th meridian. Michler completed the western half of the survey on 14 October 1855. Schott was attached to Michler's party as a surveyor and scientific collector. He collected plants, minerals, and fossils with botanist-geologist Charles Parry, as well as insects and vertebrate specimens, including amphibians and reptiles, that ultimately would be shipped back to the Smithsonian Institution. Schott was also a talented artist and prepared many color illustrations of the region's topography, vegetation, and indigenous peoples. Schott is honored in the botanical and herpetological literature, e.g., *Yucca schottii*, *Lophocereus schottii*, *Masticophis schotti*, and *Urosaurus ornatus schotti*.

The actual location of Fort Yuma (neither indicated in the original ledger nor specified by Baird [1859:6]) has also been a source of confusion for some herpetologists. Among subsequent workers who listed the type locality for *S. obesus*, Stejneger (1891), Schmidt (1922, 1953), Stejneger and Barbour (1923, 1933, 1939, 1943), Smith (1946), and Hollingsworth (1998:40) mistakenly stated that it is in Arizona, undoubtedly associating it with the town of Yuma. Van Denburgh (1922) correctly indicated its location in California, as did Shaw (1945).

The town site on the Arizona shore of the river was surveyed in 1854, and originally named Colorado City, and later, Arizona City. It was renamed Yuma in 1873 (Lamar 1977). On the other hand, Fort Yuma was established in 1852 on the California side of the river south of the Cargo Muchacho and Chocolate mountains, on a hill that originally was the site of a Spanish mission; the site intermittently became an island during floodwaters. Its purpose was to protect the ferry across the Colorado River, an important link in the livestock trails from New Mexico and Sonora to California (McKinney 1961; Wharfield 1968). Today, the renovated fort lies within the Yuma (Quechan) Indian Reservation in Imperial County.

No chuckwallas, or their scat, were observed during a recent visit to Fort Yuma. The immediate vicinity has had a history of substantial habitat disturbance; the Southern Pacific railroad cuts along the southern slope of the hill and Interstate Highway 8 passes close by. Whether chuckwallas actually occurred at Fort Yuma may never be known. Early photographs of the site (Fig. 2) suggest a paucity of suitable habitat, although these lizards occasionally occupy earthen hills and banks of large washes, using holes and crevices for shelter (Feldner and Feldner 1991; Montanucci, pers. observ.). There is one additional chuckwalla recorded from Fort Yuma; the specimen (CAS 130) was collected by F. P. McLean (date unknown), but later lost in the San Francisco earthquake and fire of 1906 (Jens V. Vindum, pers. comm.).

If one assumes that the type specimen was collected near Fort Yuma, the nearest suitable habitat exists at Pilot Knob. Therefore, an alternative explanation to be considered is that the chuckwallas procured by Arthur Schott and by F. P. McLean were actually collected at Pilot Knob, but labeled "Fort Yuma" as a consequence of the early common practice of designating the shipping point as the collection locality. Fort Yuma is known to have been an important mail post (Wharfield 1968). Pilot Knob, which has substantial rocky habitat and supports a population of chuckwallas, lies about 11.4 km west of Fort Yuma, and only 1.4 km north of the survey route traveled by Arthur Schott. The holotype, which is a female, compares favorably with living specimens photographed at Pilot Knob, but this evidence is inconclusive because females from different areas generally lack diagnostic pattern features.

The precise location of Fort Yuma may have added importance in the context of the subspecific taxonomy of these lizards. I have

noted differences in the color pattern of male chuckwallas from opposite sides of the Colorado River near Yuma. The head, neck, chest, forelimbs, hindlimbs and rump are jet black in males from both sides of the river. But in those from Pilot Knob, the Cargo Muchacho and Chocolate mountains (N = 10: 3 alcoholics, 7 voucher photos) the dorsal mid-body is cream to pale tan with dense reticulations of red. Males from the Gila Mountains (Telegraph Pass, type locality of *S. o. tumidus*), and mountains further east (N = 28: 7 alcoholics, 21 voucher photos), have a uniform red dorsal mid-body, with or without black reticulations, black spots, and white spots. These color pattern differences are obvious in living specimens, but eventually disappear in preserved material. Hollingsworth (1998) did not recognize any subspecies in the common chuckwalla, but pending further study, subspecific designations may be warranted.

In summary, Baird's (1858) description of *Euphryne obesus* is brief and incomplete; his statement "abundant in the canons of the Colorado, of California" should be interpreted as a habitat description, not as the type locality. Only by consulting both of Baird's works (1858 and 1859) can it be ascertained that Fort Yuma is the type locality and the collector of the holotype was Arthur Schott, not Major G. H. Thomas. A paratopotype listed in the 1859 work as USNM 2774 does not exist, and the museum number is erroneous. Historical records clearly show that G. H. Thomas had no involvement with the United States and Mexican Boundary Survey, or with Lt. Ives' exploration of the Colorado River. Fort Yuma is situated in California, not Arizona, and its precise location may have importance in the subspecific taxonomy of chuckwallas, as distinct populations occur on either side of the Colorado River near Yuma. The ambiguities in Baird's work have contributed to errors in the chuckwalla literature, including the most recent papers.

Acknowledgments.—My appreciation is extended to W. Ronald Heyer, Ronald I. Crombie, T. D. Hartsell, Kenneth Tighe, Robert V. Wilson, National Museum of Natural History, who kindly supplied me with information for the type material of *S. obesus* from the original catalog and computer records. John E. Simmons (KU), Hobart Smith, and R. Wayne Van Devender graciously provided me with some pertinent, but scarce, literature. I also thank the curators and curatorial staff of the National Museum of Natural History (USNM), the California Academy of Sciences (CAS), and the Los Angeles County Museum (LACM) for the loan of museum specimens, including the type material. Susan Sheehan, Arizona Historical Society, Tucson, kindly supplied photographs of Fort Yuma. Keith Ealy, Thomas C. Greb, and Scott Patterson provided able field assistance in the Cargo Muchacho and Chocolate mountains and at Pilot Knob. I am also grateful to Kevin de Queiroz and three anonymous reviewers for thoughtful comments and constructive criticisms of previous drafts of my manuscript.

Estimating Terrestrial Salamander Abundance in Different Habitats: Efficiency of Temporary Removal Methods

SEBASTIANO SALVIDIO

DIP.TE.RIS – Dipartimento per lo studio del Territorio e delle sue Risorse
Università di Genova, Via Balbi 5, I-16126 Genova, Italy

Villa Comunale ex Borzino, CP 21, I-16100 Busalla, Italy

Temporary removal methods may be used in the investigation of terrestrial salamander population dynamics (Bruce 1995; Salvidio 1998), as well as amphibian long-term population changes (Hayek 1994). In these studies, all animals captured are physically removed from the population, kept in a holding area, and relocated when the study is completed. Removal experiments usually require short sampling intervals, reduced field personnel, and are less expensive than mark-recapture studies (Hayek 1994). When basic assumptions are met (e.g., population closure, equal sampling effort, equal catchability, and effective reduction of the population after each search), the statistics calculated from removal data seem reliable. There are relatively few ecological studies on amphibian populations that use this technique and there are no comparative analyses on the efficiency of removal experiments upon conspecific populations living in different habitat types.

In this study, temporary removal data were analyzed from two populations of the European terrestrial plethodontid salamander *Speleomantes strinatii* (Aellen 1958) living in different environmental conditions: a cave environment (i.e., an artificial tunnel excavated during World War II to serve as an air-raid shelter) and a subsurface habitat (i.e., a humid rock-face). These environments constitute ends of a continuum (Culver 1986; Juberthie et al. 1980) relative to their ecological conditions. Caves are relatively simple in structure because cave walls are lacking overgrowing vegetation and salamanders are active on a completely bare surface. Also, the artificial cave has relatively constant environmental conditions: mean annual temperature is 9°C (range 5–12°C), and air relative humidity is >90% (Salvidio et al. 1994). In contrast, the rock face is structurally more complex because creepers (e.g., the English ivy *Hedera helix*), litter accumulation, and rock debris are present, providing refugia for salamanders. The rock-face is exposed to circadian and seasonal variations in solar radiation, temperature, air humidity, and rainfall. In this area, the mean annual temperature is about 12°C, ranging from 5°C in January to 21°C in July. Annual rainfall averages 1600 mm, with monthly values ranging from 40 mm in July to 200 mm in November (Brancucci 1994). Climatic events (see Salvidio 1998), vegetation growth, litter accumulation, and rock-face erosion produce small year-to-year microhabitat changes that increase habitat variability. The two sites are predicted to differentially affect resident salamander activity patterns, and hence the effectiveness of temporary removal methods.

The aim of this study was to examine the efficiency of temporary removal methods in these different environments. We predicted that removal methods would be more efficient in simple-structured and constant habitats (i.e., caves) in comparison to relatively complex and variable ones (i.e., rock faces). In particular, we hypothesized that 1) average capture probabilities would be higher in the cave environment; and 2) capture probabilities would be more variable in the rock face site.

The two study sites are located in NW Italy near Genova and are separated by a linear distance of about 10 km. The rock face habitat is located along a small stream, surrounded by mixed deciduous forest (*Castanea sativa*, *Alnus glutinosa*, *Ostrya carpinifolia*, *Fraxinus ornus*) that produces a thick vegetative cover. In both habitats, three temporary removal samples were taken each year from 1996 to 1999 by the same collector, usually every other day during the peak activity period of *Speleomantes strinatii* populations, which are in July–August and in October–November in cave and rock face habitat, respectively. The total sampled surface area was 120 m^2 in the cave and 190 m^2 in the rock face environment. Animals were located with the aid of a headlamp and collected by hand. All salamanders captured were removed, measured (snout–vent length, SVL) and housed in plastic boxes lined with wet paper towels at about 5°C. During this study, no direct mortality of the removed salamanders occurred, and at the end of the third removal sampling, all salamanders were released at their capture sites.

The SVL measurements generated polymodal frequency distribution histograms that were analyzed with the FAO-ICLARM Stock Assessment Tools (FiSAT) computer program (Gayanilo et al. 1996). This program enabled the decomposition of mixed length-frequency distributions into their Gaussian components by means of Bhattacharya's (1967) log-differences method. In all samples, three SVL groups were separated: the two smallest ones corresponding to immatures, and the largest comprising adults plus subadults (ranges of annual mean SVL in the rock face and cave populations, respectively, were: first group, 29.2–32.3 and 24.1–26.0 mm; second group, 43.2–44.3 and 33.2–37.7 mm; largest group, 58.8–62.6 and 56.2–61.9 mm).

Population abundance was estimated by means of the program CAPTURE routine M_{bh} (White et al. 1982). This routine gives the population estimate N_i, its standard error s_x, and, if at least three removal samplings are used, it allows a test for homogeneity of capture probabilities with a χ^2 goodness of fit test (White et al. 1982). In this model, capture probability (CP) is the average probability of capture of an animal, and every individual has an equal and constant CP on all removal occasions (White et al. 1982). Salamander observability (CP in this case) could be related to habitat differences and microclimatic variations in the two study sites (Conroy and Nichols 1996). Population size was estimated for the entire population (i.e., all individuals pooled) and for juvenile (i.e., the two smallest SVL cohorts) and adult components separated according to FiSAT analysis. This procedure was important, because the two salamander populations were sampled in different seasons and displayed different boundaries between adjacent SVL components.

Individuals may have been recaptured among years because *S. strinatii* are long-lived (Salvidio 1993). For this reason, successive CP values were not independent. Thus, to compare CP within

TABLE 1. Population estimates, calculated from removal data using CAPTURE routine M_{bh}, of two populations of *Speleomantes strinatii* living in different habitats. N_i = number of salamanders estimated, s_x = standard error, and χ^2 = test for homogeneity of capture probabilities among the three successive removal samples.

Habitat	Sampling year	Age class	N_i	s_x	Capture probability	χ^2	P
Rock face	1996	juveniles	72.78	23.4	0.290	0.24	0.62
		adults	31.03	5.8	0.440	0.20	0.65

and between populations, the Friedman two-way analysis of variance by ranks was used. The null hypothesis of this test was that the k repeated measures or matched groups compared came from the same population or populations with the same median (Siegel and Castellan 1988). To compare the variability of CP between populations, the coefficient of variation (CV = standard deviation/mean) was tested by a two-way ANOVA, using habitat and age class as factors.

During this study, 704 salamanders were captured, measured, and released at the two study sites. In all samples, CP values were higher than 0.20 (Table 1), a value considered adequate for estimating population abundance in removal experiments (White et al. 1982). Moreover at the end of the third removal occasion, substantial proportions of *S. strinatii* populations were removed; about 90% and 60% in the cave and rock face habitats, respectively.

Capture probabilities were not different from homogeneity in the rock face habitat ($0.06 < P < 0.82$, Table 1). In the cave, there were differences from homogeneity in three cases: in the adult subpopulations, both in 1998 and 1999 ($P = 0.01$, and $P = 0.03$), and in the 1998 total sample ($P = 0.03$). However, the analysis of capture data showed that adult salamanders were extremely catchable during the first sampling occasion, because more than 80% of the entire population was removed after the first sampling. Thus, the linearity of CP should not be of concern (Lancia and Bishir 1996). For these reasons, it was assumed that sampling protocols were adequate in yielding repeatable statistics in both habitat types. Within each population, there were no differences between adult and juvenile CP (Friedman two-way analysis of variance by age blocked by year: cave, $F_r = 1.00$, DF = 1, $P = 0.317$; and rock-face, $F_r = 0.00$, DF = 1, $P = 1.000$) allowing CP of the entire samples to be used when comparing different habitats. On average, cave population CP values were about twice those estimated in the rock face habitat (Table 2), and when the two populations were compared, CP values differed ($F_r = 4.00$, DF = 1, $P = 0.046$). In addition, salamanders living in the two habitats displayed different patterns of observability and thus of catchability.

TABLE 2. Mean capture probabilities of two *Speleomantes strinatii* populations living in different habitat types. CP = capture probability; CV = coefficient of variation; N = number of sampling years; SD = standard deviation of the mean.

Age class	N	Mean CP	SD	Range of variation	CV
Rock face population					
Juveniles	4	0.393	0.130	0.290–0.584	0.331
Adults	4	0.324	0.129	0.202–0.440	0.399
All ages	4	0.330	0.046	0.267–0.365	0.139
Cave population					
Juveniles	4	0.569	0.074	0.484–0.639	0.130
Adults	4	0.732	0.112	0.572–0.812	0.153
All ages	4	0.639	0.060	0.587–0.703	0.094

In the cave habitat, 66% of the entire population estimated was captured during the first search, in comparison to only 32% of the rock-face population. The year-to-year CP variability, expressed as the coefficient of variation, was more than two times lower in the cave than in the rock-face habitat (Table 2). However, this difference was not statistically significant (two-way ANOVA $F = 109.17$, $DF = 3$, $P = 0.062$).

In this study, the efficiency of removal methods was tested on two conspecific populations of the European plethodontid salamander *Speleomantes strinatii* living in different habitat types. The analysis of capture data showed that removal protocols were adequate in both cases. The first hypothesis (i.e., higher CP values in the more constant habitat) was supported, while the second (i.e., lower variability of CP in the more constant habitat) was not, probably because of the relative small number of years (N = 4) in which CP were calculated. Indeed, removal efficiency, expressed as the probability of observing salamanders, was enhanced in the more constant and simple-structured habitat, where a higher proportion of the salamander population was active and exposed to capture.

Temporary removal techniques have proved adequate in estimating population abundance of terrestrial salamanders (Bruce 1995; Salvidio 1998). However they are seldom, if at all, used in long-term monitoring studies, because count data that require less time and effort are usually preferred (North American Amphibian Monitoring Program 1996). Count programs appear relatively inexpensive but produce data on the surface activity pattern of salamanders rather than on their population size or abundance. However, as this study has suggested, different percentages of salamander populations may be active on the surface in different ecological conditions, and thus caution should be used when comparing salamander populations living in different environments on the basis of simple count data. In these cases, the only way to deal with unknown sources of variation in observability is to estimate the observation probabilities (i.e., capture probabilities) for the samples being compared (Conroy and Nichols 1996).

In the case of temporary removal monitoring, the field effort could be maintained similar to count programs in which successive searches are planned. The main difference probably would be a much shorter time period between successive removals to prevent immigration from adjacent plots. In addition, laboratory facilities and collecting and transport permits might be needed to displace salamanders and maintain them in captivity. In any case, population size estimates resulting from removal methods appear to be a fine method to document long-term trends and should be taken into serious consideration when planning studies monitoring amphibian population fluctuations over time, at least in temperate climates, as the efficiency of removal methods in extremely complex (i.e., tropical rainforests) and freshwater habitats remains to be tested.

Acknowledgments.—Capture permits were obtained from the Italian Ministero dell'Ambiente, Servizio Conservazione della Natura (prot. n. SCN/2D/98/14345). CAPTURE software was generously provided by the Colorado Cooperative Fish and Wildlife Research Unit. Thanks are due to Sam Droege, Deanna Olson, Kandyd Szuba, and an anonymous reviewer for comments which improved the manuscript.

In 1994 we were attempting to quantify the abundance of small lizards on Guam as a means of appraising the predatory impact of the brown treesnake (*Boiga irregularis*). Our mark-recapture effort had failed, due to an unknown combination of loss of marks and low recapture probability. We had identified several indices of lizard abundance (sightings per hour, trap captures per hour), but we were concerned that the ecological "signal" from these indices might be obscured by extraneous factors such as interobserver inconsistency, behavioral response of the lizards to detection or removal, etc. To test our indices, we elected to compare them to high validity absolute population density estimates that we obtained by an unprecedented method that we call a total removal plot: we physically isolated small patches of forest and counted the lizards encountered while we disassembled the forest leaf by leaf.

The technique worked much better than expected; we were able not only to obtain a complete count (a census) for a precisely defined area, but we also discovered an unexpectedly large number of animals. From the twenty total removal plots we have sampled on the islands of Guam, Saipan (both Mariana Islands of western Pacific), and Guana (British Virgin Islands, West Indies) to date (1995–1999), we have obtained an average of 160.5 reptile individuals per 100 m^2 plot (range 16–711). Documenting such high absolute densities has not only greatly enriched our understanding of reptile ecology, but it has also played a key role in interpreting the abundances of reputedly rare lizards to regulatory authorities hostile to scientific collecting. We are also able to quantify entire assemblages with total removal plots; previously we had to make the untenable assumption that our collecting technique worked equally well for all species of interest. The technique has also given us a tool for hard validation of myriad sampling methods. Most evaluations of sampling methods (Brown and Nichols 1993; Campbell and Christman 1982; Fitch 1992; Grant et al. 1992) are "soft" in the sense that they compare the number of specimens obtained, or the cost of the sampling tools, but they do not measure either precision or bias of the population estimate. The outcome of that omission is that one knows only the denominator (cost) of the technique's benefit-cost ratio, which promotes the use of low-cost methods that are erroneous to an unknown degree. Another soft validation approach has been to estimate the amount of bias and precision by contrasting two techniques, both of which are of unknown validity (e.g., Rotella and Ratti 1986), an approach that has drawn criticism but no practical solution (White 1992). In forthcoming papers we will report our measurements of the precision and bias of various techniques by comparing each technique to the complete census provided by total removal plots. In this work we describe our total removal method.

METHODS

The four major components of our method are: 1) plot selection, 2) plot characterization by non-destructive methods, 3) physical isolation of the plot, and 4) total disassembly and removal of all aboveground organic matter to census the inhabitants. Our method differs from traditional tropical forest litter plots (Inger 1980; Lloyd et al. 1968; Scott 1976) in that we physically isolate the plots prior to sampling them, and we remove all aboveground vegetation.

Selection of the plot site.—We sampled plots of 100 m^2 (= 0.01 ha). Larger plots are desirable from the standpoint of minimizing boundary effects, but they require substantially more work without a concomitant increase in the geographic representation of the sample. All things being equal, numerous smaller plots spread throughout a study area are more likely to reflect average conditions than are a few large ones, but small plot results may be grossly distorted by the habitat and human disturbance associated with boundary clearing. The tradeoff between minimizing boundary effects and maximizing geographic representation will have a different optimum in different habitats. Because the forest canopy

was relatively low (usually about 10 m high) in the areas in which we have worked, plots of 100 m^2 were judged to be of minimum size to permit the felling of canopy trees within the enclosed area. Larger plots would be desirable for taller canopy forest. Smaller plots might be optimal in shrubland.

We selected sites, without knowledge of reptile density, on the basis of habitat type, vegetation structure, and substrate. Habitat type (e.g., *Leucaena leucocephala* forest) was chosen on the basis of our sampling objective. Plot location was selected qualitatively to represent the average vegetative structure of the target habitat. For example, if the target habitat typically had a canopy height of 11 m and canopy coverage of about 75%, we selected a sample plot that would conform to those averages. Additionally, it was impractical to physically isolate plots that had a fissured or rocky substrate. Therefore, we positioned plots to have a sandy or earthen substrate, with minimal rock outcrops or at least rock outcrops that could be isolated. Our plots were usually 10 x 10 m, but the shape was occasionally modified to 8 x 12.5 m or a similar rectangle of 100 m^2. The actual boundary line sometimes deviated slightly from a straight line to avoid troublesome substrate or large leaning trees. Any subtractions made by deviating to the inside of the nominal boundary were balanced elsewhere by equivalent additions.

Plot characterization.—Prior to isolating each plot we sampled the reptile populations with a variety of nondestructive relative and absolute population abundance measures, and we always quantified the structure and composition of the plot's vegetation before disturbing it. At the time of vegetation removal, we weighed the fresh mass of all vegetation removed. The large quantity of wood made it impractical to obtain dry mass measurements. Careful analysis of tropical forest biomass by others (Art and Marks 1971; Lieberman and Lieberman 1994; Odum et al. 1970; Rodin and Basilevic 1968) indicates that dry forest biomass is about 50% of the fresh biomass. Fittkau and Klinge (1973) weighed each component of an Amazonian forest separately and found that only 2.2% of the fresh mass was leaves (84% stems and trunks, 7.5% litter, and the remainder vines and lianas). Thus we presume that our biomass measurements reflect primarily the amount of wood in a study plot.

Isolation of the forest plot.—The first step was to remove enough low-lying vegetation to insure that animals could not use the vegetation as a bridge across the ground level barrier that we would later put in place. The ground-level barrier we used was constructed with 508 mm wide (sold as "20 inch wide") aluminum flashing buried 50–100 mm into the ground. In other localities the height of the fence may need to be adjusted for the scansorial skills of the target species. To effect an unequivocal separation, we cleared a swath about 1.5 m wide to a height of about 2 m along the course in which the flashing fence was later placed, and excavated a furrow into which the flashing was to be inserted. Furrow excavation always revealed root obstacles, which were severed to allow the later burial of the bottom of the flashing. In addition, if the soil was shallow we placed rebar supports at places where the flashing had to bend sharply, such as the corners of the enclosure, and at especially high and low places. Generally we used 3 or 4 supports per 10 m side. Additional rebar supports were later positioned where a roll of flashing ended or began. We used rebar for the supports, but any sharpened metal post would do. The preferred length of the bar depends on the hardness of the soil or substrate. We used rebar pieces about 0.9 m long pounded vertically into the ground at the bottom of the trench such that the top of a bar was level or below the height of the flashing whenever possible. In the sandy soils present in our British Virgin Island sites we did not find it necessary to use rebar supports.

Five rules were followed to minimize the influence of this trenching/clearing activity on herpetofauna: 1) activity occurred during the day to minimize disturbance of nocturnal geckos; 2) no motorized tools were used (in our experience, chainsaws in particular induce flight in lizards); 3) brush removed at this stage was dispersed rather than being piled, so that animals would not be attracted to potential brushpile refugia; 4) half of the removed vegetation was placed within the plot and the other half was placed outside, to limit any bias this vegetation might have on lizard movements; and 5) this activity was scheduled to occur 24 h prior to initiation of vegetation removal, so that any terrestrial species disturbed by the activity would have plenty of time to regain their normal home range prior to isolation. Because heliophilic lizards were attracted to the light gap created by vegetation removal, it was deemed desirable to otherwise minimize the interval during which heliophils might colonize the light gap.

Canopy separation.—Canopy separation inevitably had an adverse effect on arboreal species. Most arboreal species in the Mariana Islands are also nocturnal. Unless physically displaced, nocturnal species did not attempt to move away from an area of daytime disturbance until the following nightfall. However, the diurnal species disturbed by daytime canopy separation moved away immediately, but returned to their home ranges if given sufficient daylight hours without a disturbance. Therefore, in areas where the arboreal species are mostly diurnal (Virgin Islands) we separated the canopy at night (at the same time we emplaced the ground-level barrier). In areas where the arboreal species are mostly nocturnal (Mariana Islands) we separated the canopy as early as possible in the day on which the barrier would be placed after nightfall. In this way, nocturnal species would have no opportunity to vacate the plot if they were disturbed by canopy separation, and diurnal species would have at least half a day to return to their terrestrial haunts after we had left the area, before we returned to construct the barrier.

Canopy separation was straightforward in principle; a gap of at least 1.5 m was created between the aboveground vegetation inside the removal plot and the vegetation outside of the plot. The gap distance had to be maintained despite wind-induced tree movements, and the distance criterion was chosen to accommodate the jumping ability of the reptile species to be isolated. Where possible, we created the gap in the foliage directly over the line on which the ground level barrier was later placed, and in forests composed of trees with vertical trunks this could be achieved. However, our sites often had trees that had partially fallen as a result of hurricanes. We attempted to minimize inclusion of leaning trees when choosing a site, but could not always avoid them. The temptation was to cut all trunks, limbs, and branches that extended over the plot boundary. However, if all stems that crossed the perimeter line were cut, the total amount of aboveground vegetation formerly within the plot would have been reduced by the amount of leaning vegetation that entered the plot's "airspace" from trunks rooted outside of the plot. Furthermore, strict bound-

ary cutting creates excessively large light gaps (altering habitat for heliophilic species). The solution we chose was to generally leave intact all stems that arose from trees rooted within the plot, regardless of whether they passed to the outside of the barrier above ground level. This insured that the amount of aboveground vegetation sampled was the same as that which would have been found in the airspace of an average 10 x 10 m column of forest. We used extended pole clippers and arborist methods (Dial and Tobin 1994) to create the canopy separation.

Installation of barrier.—We installed the aluminum flashing barriers in the first hours of darkness on the night immediately preceding vegetation removal. This insured that nocturnal species would be trapped within the sampled plot (because they are loath to crawl into the open while humans are disturbing the area). The diurnal species were also trapped because they had already cloistered themselves in their nighttime refugia by the time we began barrier installation. Because the trench to receive the barrier had already been prepared, it took only 1–2 h for a crew of four to install the fence.

Barrier installation involved eight steps in the following order: 1) flashing inserted in ground; 2) rebar supports emplaced; 3) earth tamped to hold bottom of flashing; 4) rebar tied to flashing; 5) all seams and rugosities taped; 6) lithium grease sprayed on completed fence; 7) soil at base of fence wetted and retamped for better seal; and 8) protective glueboards placed.

The aluminum flashing was rolled out by one or two persons while one or two more forced it into the trench and backfilled soil. We found that it was vastly preferable to have the fence follow a subtly sinuous path rather than run in a straight line. Sinuosity in the fence line enabled it to conform to the inevitable irregularities in the ground's height, without the necessity for seaming the flashing or creating sharp curves that lizards could climb. Sinuousity also increased the barrier's vertical stability.

Soil tamping was only partially effective if the soil was dry. We found that wetting the soil helped, but it was important to avoid wetting the soil on the first tamping, because it was very difficult to wet the soil right next to the flashing without getting the flashing wet, and wet flashing could not be greased. Also, we found that tamping had more enduring benefits if completed only after the fence was in its final position.

To tie the flashing to the rebar it was necessary to punch two small holes (about 2 cm apart, pushing from the inside to the outside of the enclosure), one on either side of the rebar. Holes punched from the outside to the inside of the enclosure tended to create a rough spot on the inside, potentially enabling a climbing lizard to gain purchase and escape; therefore, this was avoided. One pair of holes was punched 5–10 cm below the top of the rebar, the other at the base of the flashing. A 20 cm long piece of tie wire was doubled into a U-shape and pushed through the flashing from the inside. After twisting the two ends tightly together around the post, the excess was cut off, and the protruding remainder folded down flush against the rebar.

After smoothing the tie wire against the inside, a 5 x 5 cm patch of aluminum tape (such as is sold at hardware stores for patching car bodies or mufflers) was placed over the inside ties. When carefully rubbed down, this tape presented an extremely smooth surface. Aluminum tape was also used to close the seam at the ends of flashing pieces. However, aluminum tape is expensive and it does not accommodate irregular surfaces. Therefore, for the outside surfaces of the barrier we used duct tape, which covered the irregular ties, rebar, and ends of flashing rolls.

We sprayed white lithium grease on all tape and rough surfaces, as well as the top 20 cm of the fence (both inside and out).

To minimize immigration/emigration by jumping lizards, we stapled paper glueboards (Rodda et al. 1993) on all elevated surfaces near enough to the barrier (inside and out) to tempt a leaping animal.

General removal strategy and inspection notes.— Live animals are extremely easy to detect; dead ones are easily lost in the debris. Therefore, it was our first priority to keep all the animals in the plot alive. As the barrier was secure for the target species, there was little opportunity for an escape, and therefore, it was not necessary to catch each animal on first sighting. Instead, we inspected the vegetation systematically and captured the animals when it was made easy by their being "trapped" against the fence or out in the open. We found it most productive to focus our efforts on minimizing the amount of vegetation that had been cut down but not yet inspected. Inspected vegetation was placed in trash cans greased on the outside to repel climbing lizards. We found it desirable to avoid using trash cans with wheels, as it was difficult to confirm that lizards were not clinging to the inside of wheels as the filled trashcan was being taken out of the plot for weighing.

The general strategy was to work from the outside in, first by pivoting into the plot any trees that leaned out over the fence. Usually, such leaners were pulled to the inside by ropes as they were being dropped. Although lizards jumping from trees have been very rare in our experience, almost all jumping occurred at the moment when tree tops were felled. Therefore, for such moments we assigned one person to do nothing other than watch for possible escapes. Fewer than five such attempts were detected, and most of these lizards were captured on the ground. The others were visually identifiable, allowing inclusion in the population estimate.

Lizards hid in remarkably small cavities. Gaps in wood grain as narrow as 3 mm concealed small geckos. Therefore, it was necessary to inspect every surface with great care. All vegetation was cut into modest-sized pieces before being inspected. Solid woody items were generally reduced to pieces less than 1 m long; wood with crevices was chopped apart completely. Leafy branches were harder to inspect and often needed to be chopped into hand-sized pieces. We found that lizards were often concealed: within dead or live leaves that had curled, within holes in rocks (all porous surface rocks were broken apart), under rocks and roots (all were excavated to solid undisturbed soil), within tree cavities (all were split open), and under bark (all loose bark was removed). As we carried out our search, animals were eventually exposed, causing them to flee and become extremely conspicuous. In a few cases, however, small unseen lizards were unintentionally trod under foot. We believe that most of these were found, either by visual detection of the carcass, or by paying attention to aggregations of flies or ants, which generally indicated the presence of a dead animal. We found that the most effective tactic was to keep the ground clear, so that animals were not lost by being inadvertently killed while hidden under debris. We found that raking tended to bury frogs and lizards rather than reveal them, so we avoided raking.

We found that some animals reacted with extreme distress to the sound of a chain saw. Therefore, we attempted to cut all trees leaning to the outside of the barrier with a hand saw (to minimize jumpers), and we avoided using a chainsaw until all upright vegetation was well within the perimeter of the plot. In the Marianas, we also maintained glueboards against the fence, to capture fleeing lizards that might not otherwise have been seen. Glueboards were not used in the Virgin Islands, where there were saurophagous birds (Pearly-eyed Thrashers, *Margarops fuscatus*) that would dart in among the researchers to consume lizards trapped on glueboards. It was necessary to closely monitor any glueboards left in sunny places, as the solar-heated glue became excessively hot, and rapidly induced hyperthermia in immobilized lizards.

We found that the sawdust created by the chainsaw could cover the grease on the flashing and make it possible for lizards to scale the flashing. Therefore, we faced towards the flashing when using the chainsaw, directing the resultant debris spray towards the center of the enclosure. Care was exercised to keep the barrier free of scattered soil and plant debris.

After the plot was cleaned down to mineral soil, we set a new array of glueboards within the plot and left the area. These traps were checked periodically until the following morning. Occasionally, a lizard was buried during vegetation clearing and undetectable in the duff until we left the area or night fell and the lizard ventured forth, only to be snared by the traps.

Evaluation

Validation of barrier adequacy.—We created three 3 x 3 m enclosures on Guam, removed all resident lizards, stocked the enclosures with at least five skinks and five geckos, left them for 24 h to give them opportunities to escape, and then recaptured all lizards within the enclosure to assess its permeability to lizards. The lizards were not marked. Thus if a lizard of the same species and general size had intruded and replaced one that had escaped, such a turnover might have gone undetected, though such a scenario was judged unlikely because the small size of the enclosures was expected to more highly motivate lizards to escape. The three enclosures were each coated with a different type of grease: spray automotive lithium grease, a spray cooking lubricant, and hand applied automotive grease. We found that the spray cooking lubricant lost its grip on the aluminum when sunlight hit the metal, and the hand applied grease was more difficult to apply than was the spray lithium grease. Within both greased test enclosures we detected no escapes, although we prefer to use the spray grease for its ease of application and more consistent coverage.

Applicability.—As indicated above, the total removal technique is limited to sites with suitable substrate. Fissured rock and streams preclude barrier effectiveness. The technique would be difficult but not impossible to apply to tall canopy forest, for which larger plot sizes would be recommended. The technique is suitable for all terrestrial and non-volant arboreal species (both vertebrates and invertebrates, though we have not endeavored to sample the vast number of invertebrates trapped in an enclosure). The technique is of particular value to herpetologists because it provides a total count for most of the smaller species: small frogs, salamanders, lizards, turtles, small crocodilians, snakes, mammals, and all non-volant non-fossorial invertebrates. The fence would need to be increased in height or durability to restrain large or arboreal snakes, crocodilians, mammals, or high-leaping frogs. It is probably not suitable for any gliding or flying species (e.g., *Chrysopelea, Ptychozoon, Draco*, birds, and bats). Surprisingly, brown treesnakes are caught in total removal enclosures about as often as one would expect from their density (estimated by mark-recapture: Rodda and Fritts 1992), though this arboreal species is certainly capable of scaling the fence.

We were surprised by the large number of individual lizards collected by this technique (range 16–709 per 100 m^2 plot). Individual lizard species densities ranged from 1 to 676 per 100 m^2 plot (100–67,600/ha). Species that occur at densities less than about 100/ha present special difficulties in sampling. On average, one individual of such species will be found per 100 m^2 total removal plot, requiring a very large number of plots for adequate sampling. However, such species often defy enumeration by visual surveys, mark-recapture and many other collection techniques as well. It is notable that a single 100 m^2 removal plot in Amazonia revealed the presence of five individuals of one anuran that was not otherwise detected by an expedition that collected over 500 specimens (Reynolds et al. 1997); thus total removal methodology may indicate that apparently rare species are in actuality well above the low-density threshold of about 100/ha.

We have not attempted to use the technique for censusing specialized fossorial species, such as the sand skink *Neoseps reynoldsi*. The problem of fossorial species burrowing under the barrier is apparently not as limiting as one might suppose, as Mushinsky et al. (1997; Mushinsky and McCoy 1999; Sutton et al. 1999) have efficiently used similar barriers with pitfalls to census *Neoseps*.

Costs.— The materials cost for total removal sampling was minimal, as all materials except tape and grease were reused. Aluminum flashing was cleaned and patched (when necessary) with aluminum tape, but reused flashing eventually needed replacement (1999 cost about US $2/m). The much greater cost was that of labor involved in clearing the vegetation. Discovering the many animals in a rich area is very enjoyable work, and we had considerable success obtaining the services of volunteers. Our labor needs averaged 0.83 person-hours/m^2 (range 0.45–1.56). To provide a comparison with other collecting methods, we used an average of 0.97 person-hours per specimen obtained (range 0.09–1.56). However, the labor costs were not dependent on the area cleared or the specimens obtained, but on the amount of vegetation to be checked. The relationship between fresh vegetation biomass and person-hours required for complete inspection was fairly strong ($r^2 = 0.70$), yielding the equation: Predicted PersHrs = 34.85 + 0.018*(kg of fresh vegetation). In our plots, the median mass of fresh vegetation was 1529 kg, corresponding to 63 person hours of labor.

There are innumerable opportunities for conducting total removal plot sampling in areas already destined for deforestation. These provide an excellent opportunity to extract valuable information from animals that are doomed along with their habitat. However, in some cases sampling objectives may dictate population enumeration in areas not otherwise due for clearing. Because the patch size is small in relation to regenerative processes in most areas, regrowth is rapid. However, development of weeds and light gap species was encouraged by the clearing created during total removal sampling.

Comparison to alternate sampling techniques.—The method described herein has greater face validity that almost all other tech-

TABLE 1. Primary differences between total removal plots and other techniques for quantifying population attributes of herpetofauna.

Detection technique	Analytical tool	Key advantages in comparison to total removal	Key disadvantages in comparison to total removal
general collecting	species list	efficient tool for obtaining species list; provides microhabitat data	can overlook cryptic species; may have strong detection biases
general collecting	species accumulation curve	good geographic dispersion of samples	irregular and poorly defined increments of effort; may have strong observer biases
road cruising	catch per unit effort (CPUE)	less strenuous	geographic coverage, selectivity, and abundance unknown; little control over placement of samples
pitfall/drift fence array	CPUE	high specimen yield per man-h for arrays already in place	unknown detectability differences among species, among arrays, and among sample times
trap or coverboard survey	CPUE	easy to disperse traps for broad and representative geographic coverage	must make untenable assumptions about equivalence or constancy of capture probabilities
breeding pond or hibernaculum survey	count as index	many animals sampled quickly and easily	ecological density unknown and usually unknowable
visual encounter survey	CPUE	usually easy to disperse transects for broad and representative geographic coverage	unknown detectability differences among species, transects, observers, and sample times
visual encounter survey	DISTANCE analysis (estimate distance from animal to transect centerline)	usually easy to disperse transects for representative coverage	requries difficult assumption that all animals detected, and detected before movement from centerline; observer bias likely in distance estimation
trapping webs	DISTANCE analysis (traps placed in precise radial array)	quick and flexible in placement of web	requires difficult assumptions about uniformity of habitat and total capture success at center
trap or hand capture	"removal methods" (extrapolation of capture rate decline under constant effort)	estimate obtained quickly (in some cases) with relatively minimal equipment	requires sensitive assumption about constancy of capture probability
trap or hand capture	mark-recapture	may be more efficient for species at low density	requires a reliable marking technique; limited sample may force assumptions about capture probability equivalence
traditional litter plots	count	easier to obtain good ecological and geographic dispersion of sample points	requires questionable assumptions about complete capture probability; not suitable for species that hide in trees
1 m^2 sampling frames or other small transects	count	easy to obtain good ecological and geographic disperson of sample points	cannot use on large species or species that flee from investigator, use uneven substrate (sampling frame), or refuge in trees

niques, but it requires more effort. Therefore, any comparison among methods should specify greater validity and often greater cost when comparing total removal sampling to any other method. Those differences are constant from method to method and therefore have been omitted from Table 1. The greater cost of total removal sampling does not apply in all circumstances; in some soils, installation of a long drift fence with pitfalls would require more effort than that needed for a total removal plot. Other techniques (e.g., litter plots) are less work, but have so much lower success that the yield per unit effort is lower (in addition to being of poorer quality).

The use of litter plots is the sampling technique most similar to total removal plots, and some discussion is warranted to justify the additional expense of bounding a plot and removing the trees. We initially chose to remove the trees because we were interested in the relative densities of arboreal species, which are not sampled

by traditional unbound litter plots. In the process of disassembling trees we have become sensitized to the variety of ways in which traditional unbound litter plots may be undercounts of terrestrial species. For example, in our experience a surprisingly large fraction of the terrestrial individuals take refuge inside tree bases or tree cavities, or by ascending trees. These would be overlooked by traditional litter plot methods. An example of this was inadvertently provided by the clever series of litter plots conducted by Slowinski et al. (1987); they found much higher numbers of individuals of diurnal terrestrial species when they cleared the plots at night. They interpreted the difference between day and nighttime capture rates as reflecting diel arboreal movements of the target species, but another interpretation is that the sleeping animals were captured before they had an opportunity to flee into the trees (as they did during the day). We have not attempted to test this hypothesis by ringing trees with adhesive traps; such an approach would presume the absence of cavities that would allow small lizards to bypass the glue barrier by passing inside tree hollows or under glueboards. In the forests in which we have worked, it would be very difficult to have that assurance. To determine if forest removal was necessary, we attempted to collect all of the lizards from one plot using hundreds of glueboards for a week prior to disturbing the vegetation. One non-climbing skink, *Carlia fusca*, was adequately sampled by this approach, but the remaining terrestrial and arboreal species were undercounted.

Traditional litter plots are also vulnerable to the stealthy or undetected escape of individuals through the litter. For example, in the Virgin Islands we found that *Sphaerodactylus macrolepis* geckos are adept at responding to footsteps and fleeing through the litter ahead of an approaching searcher. In the absence of a barrier these diminutive lizards might exit the plot undetected. In this regard it is notable that a pioneering series of litter plots by Heatwole and Sexton (1966; Sexton et al. 1964) used a partial barrier (cheesecloth) at the perimeter of their plots, and obtained notably higher counts than have been obtained by subsequent researchers in lower Central America using unbound litter plots (Fauth et al. 1989; Heinen 1992; Lieberman 1986; Scott 1976; Slowinski et al. 1987). The most direct evidence of the difference between bound and unbound litter plots was provided by a single comparison in Amazonia by Reynolds et al. (1997). They sampled one unbound 100 m^2 litter plot and obtained three anurans, a value comparable to other litter plot samples from the Amazon (Allmon 1991; Gascon 1996; Rodríguez 1992,). However, in an equivalent-but-bound total removal plot nearby they obtained 29 anurans and one snake. Until this matter is clarified further, it seems prudent to conclude that traditional litter plot methods may be significantly undercounting stealthy species.

Animal density estimation is the dual challenge of estimating the number of animals and determining the area that such a population of animals is using. In the case of total removal plots, we obtain a census of animals from a sharply defined area. In comparison to all other methods (Table 1), total removal plots have higher face validity, though at a cost in labor and therefore geographic dispersion of samples. We think that the technique is most valuable not as an operational sampling technique for single species, but as a means of measuring the bias and precision of less expensive alternate techniques. None of the alternative techniques provide a validated means of comparing the abundances of different species, however. For operationally quantifying herpetofaunal assemblages, a total removal methodology may be preferred.

Acknowledgments.—Among the agencies that supported this work financially, through the granting or permits, or by provided access were: Andersen Air Force Base; the Commonwealth of the Northern Mariana Islands' departments of Fish and Wildlife, Lands, and Forestry; The Conservation Agency; the Falconwood Foundation; Guam's Division of Aquatic and Wildlife Resources; the US Dept. of the Interior's Office of Insular Affairs; the US Fish and Wildlife Service; and the US Navy. We would especially like to thank H. Jarecki, J. Lazell, A. P. Marshall, L. Morton, M. Ritter, and S. R. Vogt. We are enormously grateful to all of the many people that helped clear the plots, though space does not permit naming each individually. K. Dean-Bradley provided much of the data analysis. K. Dean-Bradley, M. W. Doles, M. Fall, S. J. Kot, G. Perry, F. Qualls, B. Roelle, R. Rondeau, and G. J. Wiles suggested improvements to the manuscript.

Often, researchers need to track individual animals over the course of consecutive days to measure parameters such as territory size or home range size or to determine the status of a given individual (e.g., territory holder, floater). Because multiple animals may be present within the given study area, it is obviously important to assure that the same animal is followed from day to day.

One way to keep track of individual animals is to mark them. Reptiles are commonly marked using techniques such as scale clips, toe clips, unique paint patterns and tail beads. These marking techniques all require that the animal be initially captured in order to apply the unique mark. However, it is more difficult to capture animals after they have had the experience of being captured (Marcellini and Jenssen 1991), and often, capture is needed to complete the data collection for a study. Researchers may spend excessive time at the end of a study attempting to capture animals in order to take final measurements, blood samples, etc. If these animals cannot be captured, data will be lost. Thus a technique that allows animals to be marked without the need to capture them may save time and prevent frustration in the field by allowing animals to remain naïve with respect to capture, and thus easier to catch at the end of the study than those otherwise caught at the beginning of the study simply for the purpose of marking them. Also, because of the reduced handling time, there is less opportunity for damage (e.g., tail breaks) to occur to the animal. Finally, capturing an animal prior to data collection may result in the animal becoming wary of the observer and therefore exhibiting abnormal behavior during data collection due to observer presence. We have developed a technique for temporarily marking *Anolis carolinensis* without the need for initial capture that may be applicable to other lizard species.

A rubber squeeze bulb (we used an ear bulb syringe) was placed into the widest diameter end of a fully extended (1.6 m) telescoping fishing pole (with the terminal metal eyelet removed) so that the elongated tip of the squeeze bulb was completely inside the pole with only the bulb remaining on the outside. The junction between the bulb and the pole was sealed with duct tape (Fig. 1). Once the lizard of interest was in view and relatively close (within 4 m) to the observer, a small amount of model airplane paint (Testors® gloss enamel) was drawn up into the tip of the pole opposite the squeeze bulb. Model airplane paint (with propanol as the solvent) has been shown to have no adverse affects on lizard survivorship (Jones and Ferguson 1980) as opposed to other types of paints such as those using xylene as a carrier (Boone and Larue

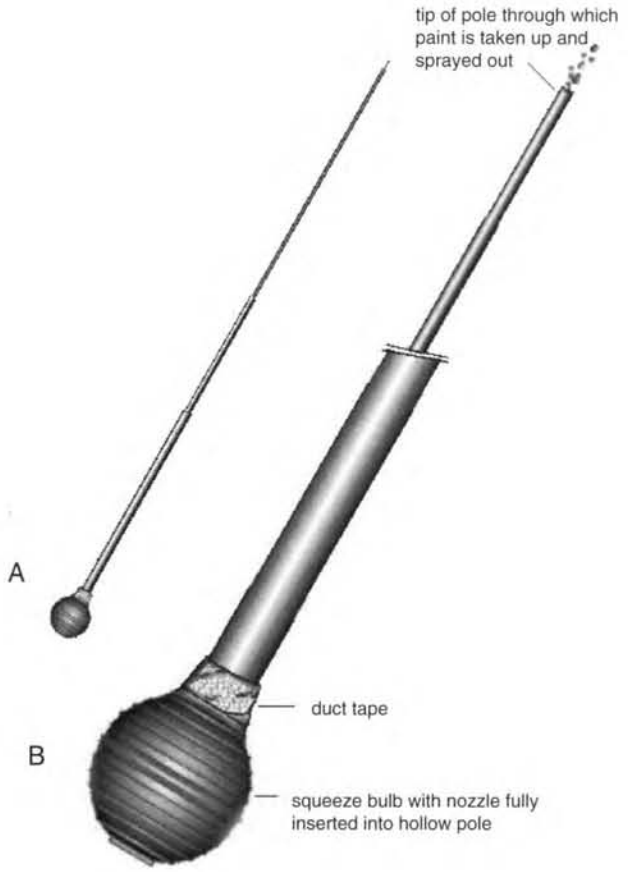

FIG. 1. Paint spraying device for temporarily marking lizards. A. Telescoping fishing pole in its fully extended (1.6 m) position. B. Enlarged view of both ends of paint spraying device.

1999). Within 60 sec of taking paint up into the pole, the tip of the pole was placed within one meter of the lizard and the bulb was quickly squeezed to release a light mist of paint. This resulted in the dorsal surface lizard becoming patterned with a number of small (<1 mm diameter) paint dots. Usually, the paint dots were not visible on the lizard unless the lizard was viewed with binoculars. The paint spray was not powerful enough to knock the lizard off of its perch, nor did the lizard move very far once sprayed (<0.5 m). Although we are not certain how long the paint took to fully dry on the lizard, we never found an animal to have smeared paint dots once it was captured at the end of the observation period.

Different animals in the same area were marked in either of two ways. In some cases, we used different paint colors for different animals. In other cases where we used the same paint color for animals in close proximity to each other, we noted the unique pattern of dots produced by the sprayed paint and used that as a means of identification once the lizards were captured.

Field studies investigating the effects of paint-marking on lizard survivorship have shown that lizards with conspicuous (brightly colored to the human eye) marks do not appear to have a reduction in survival when compared to inconspicuously marked lizards (as measured by recapture rates) (Jones and Ferguson 1980; Simon and Bissinger 1983). This lack of a survival difference has been attributed to a lack of detection by visually oriented predators (Jones and Ferguson 1980). However, we also need to consider the context in which marks will be perceived by conspecifics. Colors are recognized as indicators of status and physiological state in many animals (see Cooper and Greenberg 1992), so artificially adding color could interfere with a natural signaling system and thus affect the outcome of our studies (e.g., Burley et al. 1982). It is therefore beneficial that the marks produced by this technique are relatively inconspicuous and that multiple paints can be blended to achieve a full range of colors.

Perhaps the only caution to using this marking technique is that within 2 to 3 min of spraying the tip of the pole must be cleaned to prevent clogging. (After 60 sec with the paint at the tip of the pole, the paint would dry just enough to prevent it from being sprayed out in a fine mist at the lizard). We cleaned the pole by repeatedly (4 to 5 times) taking up thinner and spraying it back into the jar. We were able to use each 7.5 ml jar of Testors® enamel thinner to clean the pole approximately ten times.

Any marking technique that does not initially require capture of the study animals is likely to be an improvement over techniques requiring capture. Our technique is not toxic to the animal and relatively inconspicuous. It is also simple and quick to employ, requiring very little extra equipment to be carried in the field.

Acknowledgments.—We thank T. Jenssen and M. Lovern for their comments on the manuscript.

FIG. 1. Transmitter in PVC sleeve bolted directly to the carapacial margin. Note the reasonably tight fit of this unit to the shell.

than the transmitter). Next, a portion of each end of this tube was cut away to leave a flat tab extension. The tabs were drilled to accept stainless steel bolts, for attachment to holes drilled in the marginals of the turtle being tagged. The transmitter was next coated (except for the ends) with multipurpose cement (TITESEAL all purpose, T62-04) and inserted slowly into the PVC tube. After a curing period of 24 h these assembled units were engraved with a rotary tool on the upper side to identify the signal that would be given by the transmitter inside, e.g. 258. The tubing was similarly marked with bold indelible black ink to make a very visible number (Fig. 1). The completed units, which weighed about 35 g, were then bolted to the carapace through two holes drilled in the marginal scutes to the left of midline (Fig. 1) to reduce interference with mating behavior. What resulted was a very durable bond between transmitter and tubing and a solid attachment to the shell. Of seven transmitters attached in this fashion, six were found intact after one year, while only one of eight affixed with monofilament line was located.

Our attachment method could be modified to accommodate data loggers, radiotransmitters, or other small pieces of equipment. Finally, we do not endorse the use of ultrasonic tracking equipment in all situations. It is highly useful in marine habitats and some freshwater situations, but signal attentuation by vegetation, trees, brush, or other debris in seasonally inundated woodlands adjacent to rivers can make it extremely difficult, if not impossible, to locate tagged animals that move into those settings.

Acknowledgments.—We thank Carlos Crocker for help with the initial fastening of transmitters with monofilament line, and Marlin Gregor of Sonotronics for discussion which led to the more effective means of attachment reported here.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 31, Number 1 (March 2000). Submissions should be directed to one of the section editors (contact information located on inside front cover of this issue), as follows: amphibians (Painter); lizards, amphisbaenians, crocodilians, *Sphenodon* (Hauge); snakes and turtles (Butterfield).

CAUDATA

AMBYSTOMA BARBOURI (Streamside Salamander). **REPRODUCTION.** Geographically isolated populations of *Ambystoma barbouri* have recently been verified from middle Tennessee (Scott et al. 1997. Herpetol. Rev. 28:155). Information on the natural history of these populations is limited to a report by Ashton (1966. J. Tennessee Acad. Sci. 41:106–111), who commented on the unusual, stream-breeding habits of *A. texanum* in Davidson County, Tennessee. The Davidson County population discussed by Ashton is thought to be *A. barbouri* rather than *A. texanum* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington. 587 pp.). Here, we report a second breeding stream in the Central Basin of Tennessee and provide information on the timing of reproduction, egg mass size, and hatchling size.

Egg masses and hatchlings were discovered in the southernmost section of Puckett's Creek (35°49'N, 86°28'30"W), in Rutherford County, on 10 March 2000. Puckett's Creek is a first-order stream bordered by a narrow (5–30 m) strip of forest and ca. 1.0 km of field extending either to state roadways or residential housing. The eggs were found attached in a monolayer to the underside of flat rocks located in intermittent pools within the stream course. A single egg mass was collected and transported to the laboratory for rearing and confirmation. Within three days all of these eggs hatched and all hatchlings were measured (N = 51; mean TL ± 1SD = 15.6 ± 1.2 mm). Seventeen additional egg masses were located on 14 March 2000, but several were deteriorating following hatching or dehydration. Clutch sizes were estimated from ten intact masses (eggs per mass: 65, 61, 52, 16, 15, 15, 14, 8, 7, 5). Based on time of hatching and assuming a 29–82 day incubation period (Petranka, *op. cit.*), we estimate that oviposition occurred between late December and mid-February. The Middle Tennessee region is rapidly expanding. Residential construction is currently underway at the north end of Puckett's Creek, approximately 3.0 km from this unstudied population.

Submitted by **KURT J. REGESTER** and **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

PLETHODON CADDOENSIS (Caddo Mountain Salamander) and ***PLETHODON SERRATUS*** (Southern Redback Salamander). **NOCTURNAL CLIMBING ACTIVITY.** Nocturnal surface activity in the plethodontid salamander genus *Plethodon* has been well documented for a variety of species (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.; Spotila 1972. Ecology 42:95–125). Observations on the nocturnal climbing abilities of some members within this genus as well as in other plethodontids, however, have appeared less frequently in the literature (Cliburn and Porter 1986.

J. Mississippi Acad. Sci. 31:91–96; Jaeger 1978. Copeia 1978:686–691). Herein, we report on nocturnal and climbing activity in two plethodontid species taken from the same study site.

On the evening of 14 April 2000 between 2030 and 2130 h, a group of 14 observers visited an historical collection site known to harbor large numbers of both *P. caddoensis* and *P. serratus*. The locality is in the Ouachita National Forest along Forest Rd 73 (ca. 0.8 km S St Hwy 8), Montgomery County, southwestern Arkansas, USA (Trauth and Wilhide 1999. J. Arkansas Acad. Sci. 53:125–137). The sky was clear, the air temperature was ca. 17.0°C, and the ground surface litter was dry. This region of the National Forest had received moderate rainfall two days prior to our arrival. The oak/hickory forest habitat is an east-facing, moderately-sloping embankment of small, loose talus; the bank steepens sharply along an intermittent stream. Initially, we utilized an established collection technique involving the removal of surface rock in swaths to reveal salamanders hidden within the interstitial spaces of the top 20–30 cm of rock talus in the riparian zone. Although this method was successful, collectors began noticing both species of salamanders on the exposed surfaces of small-to-intermediate sized boulders. Moreover, 11 of 52 (21%) *P. caddoensis* were taken from the trunks of trees up to a height of 50 cm. In more than one instance, individuals of both species were found together on the tops of boulders. In addition to the 52 *P. caddoensis*, 45 *P. serratus* and 3 *Eurycea m. multiplicata* were found at this streamside habitat.

Jaeger (1978. Copeia 1978:686–691) noted that terrestrial salamanders (e.g., *P. cinereus*) that climb plants at night consume a significantly larger volume of food than do non-climbing conspecifics. An apparent lack of aggressive behavior between *P. caddoensis*, a larger species (in our sample, average SVL 37.33 ± 10.6 mm; range 16–52) as compared to *P. serratus* (28.16 ± 8.75; range 18–45), presumably allows each species to coexist syntopically both above and below the ground surface.

We thank the Department of Biological Sciences, Arkansas State University, for providing financial support for this field study.

TRITURUS MARMORATUS (Marbled Newt). **PREDATION.** Adult European newts typically feed on earthworms, insects, and other invertebrates (Griffiths 1996. Newts and Salamanders of Europe. T & A.D. Poyser. London). Additionally, some studies have reported intra- and interspecific predation by adults on larvae, as well as predation by larvae on larvae. However, predation by adults on adults seems exceptional (Crump 1992. *In* Elgard and Crespi [eds.], Cannibalism: Ecology and Evolution Among Diverse Taxa, pp. 256–276. Oxford University Press. New York).

During a newt survey in June 1999, we netted a bulky adult female *Triturus marmoratus* (SVL ca. 80 mm), in Veneros Lake (Asturias, Northern Spain, 43°10'N, 5°54'W; elev. 1300 m). After a few minutes, the female regurgitated a gravid female *T. alpestris* (Alpine newt), SVL ca. 55 mm, with the anterior body, including the head and forelegs, in an early stage of digestion (prey:predator SVL ratio 0.68).

Submitted by **GERMÁN ORIZAOLA** and **CARLOS RODRÍGUEZ DEL VALLE**, Departamento de Biología de Organismos y Sistemas (Unidad de Zoología), Universidad de Oviedo, c/ Catedrático Rodrigo Uría s/n, 33071 Oviedo, Spain; e-mail (GO): orizaola@correo.uniovi.es.

ANURA

BUFO BOREAS (Western Toad). **PREDATION.** In Oregon and throughout much of its range in the northwestern United States and western Canada, the Columbia spotted frog (*Rana luteiventris*) commonly shares breeding sites with the western toad (*Bufo boreas*) (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press. Moscow. 353 pp.; Green and Campbell 1984. The Amphibians of British Columbia. British Columbia Provincial Museum. Handbook No. 45. 101 pp.). Previous diet analyses of *R. luteiventris* have not reported western toads among items consumed, and suggest they rarely consume vertebrate prey. Here I report *R. luteiventris* predation on metamorphic and late-larval *B. boreas* at a site near Anthony Lake (elev. 2160 m; Baker County) in northeastern Oregon, USA. On 8 August 1998, I observed four adult *R. luteiventris* in hydrophytic vegetation adjacent to an aggregation of metamorphic *B. boreas*. More than 150 *B. boreas* (14–17 mm SVL; Gosner stage 43–45) were densely packed into ca. 1.5 m^2 along the marsh shoreline. One adult female *R. luteiventris* (85 mm SVL) ingested two toadlets from this aggregation during about 15 minutes. I disturbed a second adult female *R. luteiventris* (83 mm SVL), who swam from her position near the *B. boreas* aggregation to a refuge in submerged vegetation. After remaining motionless underwater for about 20 seconds, the frog ingested a *B. boreas* tadpole (Gosner stage 40–41) that swam directly in front of her. Neither spotted frog regurgitated the *B. boreas* before, during, or immediately after the 5 minutes associated with capture and measurement.

With the exception of one observation of cannibalism (Pilliod 1999. Herpetol. Rev. 30:93) and one report of an 'unidentified anuran' among stomach contents (Whitaker et al. 1983. Northwest. Sci. 57:147–154), vertebrates have not been documented as prey of *R. luteiventris* (Miller 1978. Northwest. Sci. 52:243–249; Turner 1959. Amer. Midl. Nat. 61:403–413; Moore and Strickland 1955. Amer. Midl. Nat. 54: 253–256). Many *Bufo* species are known to possess dermal compounds that make them unpalatable to certain predators, and deterrence effectiveness can vary with *Bufo* phenology and feeding mode of the predator (Brodie et al. 1978. Herpetologica 34:302–306; Licht and Low 1968. Copeia 1968:547–551; Wassersug 1971. Amer. Midl. Nat. 86:101–109). These observations suggest that adult *R. luteiventris* at this site are not deterred by unpalatable skin compounds in larval and metamorphic stages of *B. boreas*, and that this predator may seek young toads during the short temporal window when they are available at montane sites.

I thank Allison Kuehl for her support and help with fieldwork, and Erik Jules and R. Bruce Bury for constructive comments. Funding for this work was provided by the U.S. Forest Service.

Submitted by **CHRISTOPHER A. PEARL**, USGS, Forest and Rangeland Ecosystem Science Center, 3200 SW Jefferson Way, Corvallis, Oregon 97331, USA.

BUFO MARINUS (Marine Toad). **FEEDING BEHAVIOR.** *Bufo marinus* is reported to feed on a large variety of prey items throughout its range (Alexander 1964. Herpetologica 20:255–259; Campbell 1998. Amphibians and Reptiles of Northern Guatemala, the Yucatan, and Belize. University of Oklahoma Press Norman, pp. 68–69; Jaeger 1976. Copeia 1976:833–834). Herein we report an unusual instance of *B. marinus* preying upon a large column of army ants (*Eciton* sp.).

On 11 May 2000 at ca. 1900 h we observed a single *B. marinus* consuming army ants as the ants traveled along the bank of Lake Shimigay, Departamento Loreto, Peru. The lake is located on the southern bank of the Rio Napo ca. 1 km southeast of the village of LLChanga.

After the toad fed upon the ants for several minutes, the ants began attacking the toad. The attacking ants prompted the toad to leap ca. 1 m into the shallow water along the edge of the lake, where it began using its forelimbs to brush the attacking ants off of its body. A few minutes later the toad returned to the army ant column and resumed feeding.

Submitted by **WINSTON CARD** and **BRIAN AUCONE**, Dallas Zoo, Department of Herpetology, 650 R.L. Thornton Freeway Dallas, Texas 75203, USA; e-mail: reptiles@airmail.net.

HYLA CADAVERINA (California Treefrog). **PREDATION.** On 14 March 2000, a 30 cm green sunfish (*Lepomis cyanellus*), a non-native predatory fish, was observed in a pool with a light colored object protruding from its mouth. The pool (2.5 m L x 1.5 m W x 30 cm deep) is located in Cedar Creek in the Cleveland National Forest (T13S R3E NE1/4 Sec 31), San Diego County, California, USA. Upon capture it was noted the right rear foot of an adult *H. cadaverina* was extended from the mouth of the sunfish. The fish was photographed, and the partially digested treefrog remains were removed and preserved in 70% ethanol. The right rear foot that had not been ingested showed no sign of digestion, suggesting the treefrog was captured while still alive. *Taricha torosa*, *Bufo boreas*, and *Hyla regilla*, other native aquatic-breeding amphibians, also occur at this site. A slide of the *L. cyanellus* (with the *H. cadaverina* foot extending from its mouth) and the *H. cadaverina* remains were deposited in the California Academy of Science as vouchers (CAS 211867).

Submitted by **EDWARD L. ERVIN** and **ROBERT N. FISHER**, U.S. Geological Survey, Department of Biology, San Diego State University, San Diego, California 92182-4614, USA, and **KYLE MADDEN**, NSW National Parks and Wildlife Service, P.O. Box 1967, Hurstville, Australia.

LYSAPSUS LIMELLUS (NCN). **REPRODUCTIVE TRAITS.** *Lysapsus limellus* is restricted to areas along the Paraguay and Paraná Rivers, from Rondonia and Matto Grosso (Brazil) to central Argentina. Within Argentina, *L. limellus* occurrs in the provinces of Chaco, Formosa, Corrientes, and Santa Fé, and north of Buenos Aires (Cei 1980. Amphibians of Argentina. Monit. Zool. Ital. (NS) Monog. 2: 609 pp.). *Lysapsus limellus* is very aquatic, occurring in semi-permanent and permanent ponds (Hamann and Kehr 1997. Herpetol. Rev. 28:85; Kehr and Basso 1990. Copeia 1990:573–575.). Herein we report the first reproductive traits of the species.

Between February 1995 and November 1997, in seven samples, we collected 91 specimens (43 males and 48 females). Fifteen gravid females were collected on the following dates: 17 Feb 95 (N = 5), 28 Nov 95 (N = 3), 24 Feb 97 (N = 2), 10 Mar 97 (N = 1), 9 Apr 97 (N = 1), 4 Nov 97 (N = 2), and 13 Nov 97 (N = 1). The samples were taken in four permanent and one semipermanent ponds located ca. 15 km from Corrientes city (27°30'S, 58°45'W), province of Corrientes, Argentina. Frogs were captured by hand between 2000 and 2200 h, preserved in 10% formalin, and deposited in the CECOAL (Centro de Ecología Aplicada del Litoral) collection (frogs captured 1995 in lot #026; 1997 in lot #544). Gravid females were 17.8–29.2 mm SVL (mean 20.2 mm; SD 2.7 mm), body mass was 0.34–1.67 g (mean 1.09 g; SD 0.37 g), mature ova count range was 35–131 (mean 76.3; SD 28.6), and ma-

TABLE 1. Length, weight, and fecundity data for 15 gravid female and 43 male *Lysapsus limellus*. Date = date of capture and pond type; Sex = sex of specimens; SVL = mean snout-vent length ± one standard deviation; WT = mean body weight ± one standard deviation; Ova Number = mean mature ova number ± 1 SD; Diameter Ovum = mean diameter mature ovum ± 1 SD.

Date	Sex	SVL (mm)	WT (g)	Ova Number	Diameter Ovum (mm)
02/17/95	Female (N = 5)	19.5 ± 1.4	0.94 ± 0.11	74.2 ± 27.3	0.583 ± 0.05
Permanent	Male (N = 9)	16.3 ± 1.9	0.58 ± 0.15	—	—
11/28/95	Female (N = 3)	20.5 ± 0.8	1.46 ± 0.17	61.33 ± 17.5	0.632 ± 0.03
Permanent	Male (N = 0)	—	—	—	—
02/24/97 and 03/10/97	Female (N = 3)	20.0 ± 1.3	1.4 ± 0.60	106.3 ± 39.3	0.610 ± 0.03
Permanent	Male (N = 6)	15.3 ± 0.8	0.784 ± 0.24	—	—
04/09/97	Female (N = 1)	29.2	1.67	46	0.736
Semipermanent	Male (N = 19)	17.4 ± 1.0	1.34 ± 0.18	—	—
11/04/97 and 11/13/97	Female (N = 3)	18.4 ± 0.8	0.863 ± 0.18	75 ± 14.4	0.553 ± 0.03
Permanent	Male (N = 9)	17.6 ± 1.2	1.12 ± 0.16	—	—

ture ovum diameter range was 0.52–0.73 mm (mean 0.6 mm; SD 0.06 mm). Male SVL (N = 43) range was 13.8–19.5 mm (mean 16.99 mm; SD 1.44 mm) and body mass range was 0.43–1.5 g (mean 1.07 g; SD 0.35 g). There was significant difference in SVL between gravid and non-gravid females (t-test 5.3, df 46, $p < 0.001$), but no significant difference between body mass (t-test 0.88; df 46, $p > 0.05$). The difference in SVL between males and gravid females was significant, with females larger (t-test -5.84; df 56, $p < 0.01$), while the difference between these groups in body mass was not significant (t-test -0.25; df 56, $p > 0.79$). Furthermore, no significant difference was observed in SVL or body mass between males and non-gravid females (SVL [t-test 1.65; df 74, $p > 0.05$]; body weight [t-test 0.93; df 74, $p > 0.05$]). Finally, *L. limellus* has a reproductive mode that is characterized by eggs deposited freely in lentic water (Duellman and Trueb 1986. Biology of the Amphibians. McGraw Hill Book Co., 670 pp.). Table 1 summarizes the number and morphometric features of gravid females and males captured by each sampling date and pond type.

We thank Marta I. Duré and Monika I. Hamann for helping with laboratory and fieldwork.

PELOBATES CULTRIPES (Iberian Spadefoot Toad). **PREDATION**. Data on predation of amphibian eggs by other amphibians are scarce. Reports documents newts and salamanders as well as large anuran tadpoles feeding on amphibian eggs (Walters 1975. J. Herpetol. 9:267–279; Crump 1983. Am. Nat. 121:281–287; Denton and Beebee 1991. Amph. Rept. 12:111–112).

On 2 April 2000, at 2130 h, in a large (ca. 75 m x 30 m) ephemeral pool near Valdemanco (Madrid Province, Spain, UTM 30TVL4623), which is used for reproduction by at least six species of amphibians (*Pleurodeles waltl*, *Triturus m. marmoratus*, *Bufo calamita*, *Hyla arborea*, *Pelobates cultripes*, and *Rana perezi*), I observed one male and two female *T. marmoratus* feeding on an egg clutch of *P. cultripes*. The clutch had not been recently laid, so the gelatin that protects the eggs was disintegrating, thus facilitating the attack on the eggs.

Other adult *T. marmoratus* were observed in the same pool in the vicinity of *Pelobates* clutches, although direct feeding behavior was observed in only one case. In the same pool there were several clutches of *B. calamita*. No adult *T. marmoratus* were observed near them, although it has been reported that *T. marmoratus pygmaeus* occasionally feeds on *B. calamita* eggs (Díaz-Paniagua *in* Tejedo 1991 Herpetologica 47:322–327).

No data are available on the occasional predators of *Pelobates* eggs, nor on *T. marmoratus* feeding on other amphibian eggs. Predation by other amphibians may be common in temporary ponds, where competition for resources is expected to play a major role in survival. In this context, strategies reducing the risk of predation on eggs and embryos would be highly advantageous. This strategy has been adopted by *B. bufo* and *B. calamita*, whose eggs are unpalatable for some *Triturus* species (Denton and Beebee, *op. cit.*). Data on relative unpalatability of *Pelobates* eggs are not available.

I thank B. Lorente and I. Urbán for field assistance. This work was supported by a Comunidad de Madrid-Museo Nacional de Ciencias Naturales predoctoral fellowship in the project PB97-1231.

PSEUDACRIS TRISERIATA (Western Chorus Frog). **CALLING SITES AFTER DROUGHT**. Illinois experienced severe drought during the last half of 1999. Low precipitation during fall and winter can affect late-winter and early-spring breeding amphibians. In Illinois, *Pseudacris triseriata* breeds from mid-February into May (Phillips et al. 1999. A Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8. 300 pp.). Males typically call from the water of shallow, vegetated temporary pools, but also may call from human-made ponds and lakes (Pope 1964. Amphibians and Reptiles of the Chicago Area. Chicago Nat. Hist. Mus., Chicago. 275 pp.; Smith 1961. Bull. Illinois Nat. Hist. Surv. 28:1–298; Whitaker 1971. J. Herpetol. 5:127–150).

During the night of 26 March 2000, we made observations on two choruses of *P. triseriata* on the northwest side of Dawson Lake in Moraine View State Park, McLean County, Illinois, USA (T23N R4E Sec 26). The first chorus was in a human-made pond adjacent to the lake. Due to below average precipitation in early spring and drought conditions the preceding fall and winter, the water had receded from the vegetated shore and left large areas of barren ground. There was no emergent or submerged vegetation in the water, only sparsely scattered debris. Some males called from the water, often while located near debris floating near shore. However, most called from atypical terrestrial sites. Males called from vegetation ca. 4 m from water, from above-ground positions on the barren bank, and from a few cm below ground in cracks in the mud. We believe this to be the first report of subterranean calling by *P. triseriata*.

The second chorus was in a wooded area adjacent to a flooded stream ca. 1 km to the west of the first chorus. At this location, males called from quiet, shallow water with abundant emergent and submerged vegetation. The calling sites in this temporary breeding pool were more characteristic of *P. triseriata*, and there appeared to be no shortage of oviposition sites.

Our observations suggest that early breeding amphibians are more susceptible to the effects of fall and winter drought in man-made impoundments than in more natural habitats. During drought periods, water levels decrease and water recedes . Temporary pools form quickly during rains whereas ponds and lakes can take long periods to refill or develop new vegetation. *Pseudacris triseriata*, like many other amphibians, requires submerged vegetation or stems to oviposit (Gosner and Rossman 1959. Copeia 1959:263–266). Further, since the egg complement of *P. triseriata* is deposited as several small egg masses (Wright and Wright 1949. Handbook of Frogs and Toads of the United States and Canada. 3rd ed. Comstock, Ithaca, New York. 640 pp.), the availability of oviposition sites may be a critical factor in determining reproductive success in an area. Without the necessary conditions for oviposition, the area becomes undesirable for breeding. Individuals that breed in temporary pools may not be as strongly affected by fall and winter drought as those that breed in ponds and lakes.

RANA CATESBEIANA (Bullfrog). **TADPOLE DEPTH RECORD**. On 20 Nov 1999, while SCUBA diving at 35 m, one of us (DW) noted tadpoles associated with sunken tree stumps and lying on the bottom of Wolf Lake (elev. ca. 1006 m) ca. 12.4 km (air) east of Tuckasegee, Jackson Co., North Carolina, USA. Returning on 12 Dec 1999, DW collected two tadpoles in the southwest corner of the lake (ca. 35°13'23"N 82°59'49"W) at a depth of 32.6 m where the water temperature was ca. 7.8°C. At that depth, the tadpoles would have been subjected to a pressure of 3.2 atm. These tadpoles were catalogued in the North Carolina Museum of Natural Sciences (NCSM 60268).

The maximum depth selected by the tadpoles of any species is surely an indication of that species' overall physiological plasticity, yet there are few data recorded for this parameter. Richmond et al. (1999. Herpetol. Rev. 30:90–91) recorded *Bufo americanus* at a depth of 8 m.

RANA CATESBEIANA (Bullfrog). **FEMALE VOCALIZATION**. Female reciprocal calls have been described for 14 anuran species (Schlaepfer and Figeroa-Sandí 1998. Copeia 1998:1076–1080 and references therein). Vocalizations by female bullfrogs (*Rana catesbeiana*) have been reported, but only in the laboratory (Capranica 1968. Behaviour 31:302–325). Since 1985, we have been conducting a long-term study of population dynamics and reproductive behavior in a population of bullfrogs at Lake Sasajewun (45°35'N, 78°30'W) in Algonquin Provincial Park, Ontario, Canada. To study reproductive behavior, the breeding population of bullfrogs is censused nightly during the chorusing season. Here we describe observations and circumstances of calling by a female in this population.

On 27 June 1999, between ca. 0400 and 0430 h, we observed a female bullfrog produce vocalizations resembling the male bullfrog advertisement call while she was located within an active chorus of male bullfrogs. The female's call was qualitatively similar to the stereotypical male bullfrog advertisement call, although it was weaker in intensity, higher in pitch, and consisted of only one croak. We have occasionally heard female bullfrogs make similar-sounding vocalizations in the lab. While vocalizing, the female maintained the characteristic "low" posture that female bullfrogs use when moving within an active male chorus (Emlen 1976. Behav. Ecol. Sociobiol. 1:283–313). She also expanded her throat, although not to the same degree as males do when producing an advertisement call.

The female had been captured earlier in the night (26 June 1999 at ca. 2315 h) when we were conducting a nightly census of the population of chorusing male bullfrogs. Although it had not been possible to measure her snout-urostyle length (SUL), her mass was 300 g, the heaviest mass recorded for a bullfrog from this population during our 15-year study (R. J. Brooks, unpubl. data). The female was in the midst of a local chorus of 5 males and was nearest to a male with whom she later mated. This territorial male (identified by the unique ventral alphanumeric tattoo, C12) was the largest (SUL 119 mm, mass 155 g) of the 88 males that participated in chorus activity on Lake Sasajewun that night, and was 13 mm longer and 58 g heavier than the next largest male within the local chorus of 5 males.

Males in this local chorus responded to the female's vocalizations immediately, although none of the other 83 males present reacted. On each of the three occasions that the female was seen calling, at least two of the five nearby males (but never the large territory holder, C12) rapidly approached to within ca. 1 m of the female's position and began to produce advertisement calls. C12, seemingly alerted to their intrusion into his territory by their calls, then chased these males away with either territorial calls or bouts of wrestling. During each of these moments of male–male aggression, the female moved away from the group of males. After the last call by the female, C12 wrestled with two of the males present and then moved ca. 5 m away from the group of males and the female, repeatedly making advertisement calls. After ca. 2–4 min, the female swam toward C12 until she was roughly halfway between him and the other males, who were still wrestling. Then C12 approached to within 10 cm of her, made one advertisement call and attempted, unsuccessfully, to amplex her. The female dived and surfaced ca. 1 m away from C12. The male then repeated the approach, call and grasp behaviors, this time successfully. This sequence of behaviors is unusual in that it is typically the female bullfrog that initiates amplexus (Emlen, *op. cit.*). Within 5 min, the amplexed pair had started to lay an egg mass (ca. 0435 h). After they had finished, the female was recaptured and weighed at 220 g, demonstrating that she had lost approximately 80 g during egg-laying, 27% of her pre-amplexus body mass. This is the largest investment in reproduction ever recorded for a female from this population (R. J. Brooks, unpubl. data).

In other anurans, female reciprocal calls often elicited increased vocal activity in neighboring males (e.g., Roy et al. 1995. Curr. Sci. 69:265–270), although it is unclear whether there was an accompanying increase in male–male physical aggression. There was no indication from our observations that the female bullfrog and her eventual mate exchanged calls as a precursor to amplexus as is the case in *R. virgatipes* (Given 1993. Anim. Behav. 46:1139–1149). Our observations suggest that the female bullfrog's vocalizations incited high levels of aggressive, physical male–male competition. This advertisement vocalization is probably rare among female bullfrogs as it was not reported by previous detailed field studies of bullfrog reproductive behavior (e.g., Emlen, *op. cit*; Howard 1978. Evol. 32:850–871; Ryan 1980. Copeia 1980:108–114). However, such vocalizations may be more common among very large and old females because they have a large investment in current reproduction and a low probability of surviving the next winter. In such cases, failing to mate with a high quality male may incur significant fitness costs (e.g., high predation of eggs by the leech, *Macrobdella decora*; see Howard 1978. Ecol. 59:789–798). It is also possible that we will more frequently observe female vocalization now that this behavior has been documented.

We thank the staff at the Wildlife Research Station in Algonquin Park for their conscientious, and often unrecognized, support of

the many research programs that are conducted there.

CROCODYLIA

CROCODYLUS MORELETII (Morelet's Crocodile). **BEHAVIOR**. On 2 September 1998 at ca. 2345 h, we found a pod of hatchling Morelet's crocodiles concealed in dense aquatic vegetation (primarily *Typha* spp.) ca. 3 m from a recently excavated nest at Gold Button Lagoon (17°55'N, 88°45'W), Orange Walk District, Belize. Sixteen hatchlings were collected for mark-recapture purposes. Upon capture each hatchling vocalized, and vocalizations continued several minutes after animals were placed in a holding bag. Shortly after vocalizations began, a large crocodile (eyes and snout visible only) ca. 50 m from the bank began swimming slowly toward our canoe. The crocodile approached to within 20 m, stopped, and remained there until we left the area (30 minutes later).

On 9 September at ca. 0130 h, we returned to the same area and spotted two hatchlings ca. 20 m from the nest site. A large crocodile (eyes and snout visible only), presumably the same animal observed previously, was observed in close proximity (< 1 m) to the hatchlings. As our canoe approached, the large crocodile submerged and we captured the hatchlings, which vocalized during and after capture. As we then paddled to the nest site to search for more hatchlings, the large crocodile surfaced < 1 m from the canoe. We noticed a white, linear scar on the crocodile's left premaxillary region. The crocodile made no attempt to approach closer, and we slowly left the nest site. The crocodile then followed us for ca. 75 m into a small cove and finally stopped as we moved into shallow (< 0.5 m) water. In this cove, we collected more hatchlings, which also vocalized. After ca. 30 min, we began paddling out of the cove, and the large crocodile resurfaced < 1 m from the canoe. As we slowly passed by, the crocodile lunged and bit the side of the canoe. We continued paddling out of the cove, and the crocodile followed for ca. 75 m, until we had passed the first nest site.

On 23 and 24 September at ca. 2330 h, we returned to the nest site in a fiberglass boat powered by a 12-volt trolling motor. On both nights, the large crocodile (identified by the scar) quickly approached to within 1 m and followed for ca. 50 m as we moved through the area. On more than one occasion, the crocodile was nudged with a paddle and did not respond. At one point on 24 September, the crocodile surfaced (head only) directly in front of the boat and did not submerge as the boat passed directly over it.

On 25 September at ca. 2230 h, we returned to the nest site. The same crocodile approached the boat and was captured with a breakaway cable snare. During capture, the crocodile bit a hole in the hull of the boat. Cloacal examination revealed the crocodile (148.5 cm SVL, 290.0 cm TL) to be a male. The animal was marked and released at the site of capture.

On 6 October at ca. 2300 h, we returned to the nest site. As we approached to within ca. 75 m, we observed a large crocodile (head visible only) rapidly swimming away and submerging. Although we were unable to move close enough to positively identify it, we speculate that this was the same animal seen on previous nights, as no other large crocodiles had been observed in the area. During a 30 min search of the area, we saw no sign of the crocodile.

Female Morelet's crocodiles will defend both nests and young (Alvarez del Toro 1974. Inst. Mexico Rec. Nat. Renov. 70 pp.; Hunt 1975. Copeia 1975:763–764; Perez-Higareda 1980. Bull. Maryland Herpetol. Soc. 16:52–53; Platt 1996. The Ecology and Status of Morelet's Crocodile in Belize. Unpubl. Ph.D. dissertation. Clemson University), but to our knowledge parental care by males of this species has not been reported. Parental care by other male crocodilians has been previously observed (Garrick and Lang 1977. Amer. Zool. 17:225–239; Lang et al. 1986. Nat. Geog. Res. 2:519–525; Rom Whitaker, pers. comm.) but this behavior is not believed to be widespread among all species. We suspect the crocodile observed here was the male parent of the hatchlings we collected, and the aggressive behavior displayed was in response to the distress vocalizations of its young. Also of note was the absence of the crocodile at the site following its capture. Capture may induce wariness in crocodilians (Webb and Messel 1979. Aust. Wildl. Res. 6:227–234; Santiago et al. 1998. J. Herpetol. 32:320–324), and we suspect this to be the case here.

We thank Ruben Arevalo for assistance in the field, and Mark and Monique Howells for logistical support. Jeff Lang and Rom Whitaker are thanked for reviewing an earlier draft of this manuscript. Research and collection permits for this project were issued by Rafael Manzanero and Emil Cano, Forest Department, Conservation Division, Ministry of Natural Resources, Belmopan, Belize. Support for this research was provided by Lamanai Field Research Center, Indian Church, Belize and U.S. EPA (Grant no. R826310 to STM). Support for SGP was provided by Wildlife Conservation Society.

TESTUDINES

CARETTOCHELYS INSCULPTA (Pig-nosed Turtle). **ECTOPARASITES**. On 26 October 1996, two leeches were collected from two adult female *Carettochelys insculpta* captured in the Daly River at Oolloo crossing, Northern Territory, Australia. The river at this site is characterized by clear, shallow water during the dry season (when the leeches were collected) and deep turbid water during the wet season. The Daly possesses sandy and rocky substrates, is ca. 70 m wide, and averages 1.5 m deep during the dry season. Aquatic vegetation is mostly *Vallisneria* sp., which is extensively grazed upon by the omnivorous *C. insculpta* (Welsh 1999. Resource Partitioning among the Freshwater Turtles of the Daly River, Northern Territory. Ph.D. dissertation, University of Canberra, Canberra, Australia. 101 pp.). The first leech was found affixed to the neck of one turtle, whereas the second leech was attached to the forelimb of the other. The leeches were placed in 95% ethyl alcohol, and were subsequently identified as *Placobdelloides bancrofti*. According to Sawyer (1986. Leech

Biology and Behaviour, Vol. 2, Feeding, Biology, Ecology, and Systematics. Oxford University Press, New York, New York. 754 pp.), this leech species has not been collected since the original description from the host turtle *Emudura krefftii* in the Burnett River, Queensland, Australia. Thus, we document a new host record and range extension for *Placobdelloides bancrofti*, and the first hirudinean parasite for *Carettochelys insculpta*. Leeches were deposited in the reference collection of R. W. Davies at Monash University, Melbourne, Australia.

We thank Ron W. Davies for identifying the leeches and Christopher Shewchuk for reviewing a draft of the manuscript.

CHELYDRA SERPENTINA (Common Snapping Turtle). **DENSITY and BIOMASS**. Snapping turtle densities have previously been estimated to be 0.17/ha (Pearse 1923. Ecology 9:24–28), 1.2/ha in South Dakota (Hammer 1969. J. Wildl. Mgmt. 33:995–1005; standing crop biomass, 9.1 kg/ha, calculated by Iverson 1982. Oecologia 55:69–76), 7.3–8.0/ha in Michigan (20.6–21.6 kg/ha; Congdon et al. 1986. Amer. Midl. Nat. 115:165–173), 6.8–13.3/ha in South Carolina (15.9–33.9 kg/ha; Congdon et al. 1986, *op. cit.*), and at least 59/ha in Tennessee (Froese and Burghardt 1975. Herpetologica 31:204–208; 181 kg/ha estimated by Iverson 1982, *op. cit.*). While trapping for turtles for reproductive studies in a 0.71 ha pond in the Blue Creek drainage, 16.9 km NNE of Oshkosh, Garden Co., Nebraska, USA, we discovered a population of snapping turtles so dense as to interfere with efficient trapping of other turtles. We therefore removed all trapped snapping turtles and held them for subsequent live release. Between 31 May and 5 July 1999, we removed and measured 36 snappers (15 male, 14 female, 7 uncertain sex; 15.6–40.4 cm maximum carapace length), estimated to weigh 171.3 kg. Because of the large mesh size on our traps (50 mm), these data certainly represent minimum numbers present. Thus, the minimum density of snapping turtles in this pond was 50.7/ha, similar to the estimate from Tennessee (Froese and Burghardt 1975, *op. cit.*). However, because of the larger body size of Nebraska turtles, standing crop biomass was considerably higher, at nearly 242 kg/ha. This value is substantially higher than the mean biomass of 102.1 kg/ha (maximum, 586 kg/ha) for 49 populations of 33 species of turtles reviewed by Iverson (1982, *op. cit.*).

We thank Kay and Myron Peterson for permission to study turtles on their ranch.

IVERSON, DAMON HEARNE, JESSA WATTERS**, Department of Biology, Earlham College, Richmond, Indiana 47374, USA (e-mail: JohnI@Earlham.edu), **DEAN CROSHAW**, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, USA, and **JASON LARSON**, Department of Zoology, Miami University, Oxford, Ohio 45056, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). **AERIAL BASKING.** Carr (1952. Handbook of Turtles. Cornell Univ. Press, Ithaca, New York. 542 pp.) characterizes *Sternotherus odoratus* as "a highly aquatic species, being one of the few turtles that apparently never bask in the sunshine." Ernst et al. (1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 578 pp.) state that the *S. odoratus* basking habit is poorly developed and that they are rarely found out of water. During an 18-year study (1965–1983) of *S. odoratus* in Pennsylvania there were only 16 observations of aerial basking (Ernst 1986. J. Herpetol. 20:341–352; Ernst, pers. comm.), all of which occurred in the AM and were concentrated in April and May, when air temperatures ranged from 19.8 to 22.2°C. Typical aquatic basking, with the turtle floating at or just under the surface or clinging to near-surface aquatic vegetation, was more prevalent from June through August (112 observations), with water temperatures ranging from 18.5 to 24°C.

Here, I report more frequent aerial basking in *S. odoratus*. During intensive summer stream surveys that incorporated use of skin-diving gear, 15 *S. odoratus* were observed aerially basking within a 2500 m section of the North Fork of White River, Ozark Co., Missouri, USA. All observations were made between 26 June and 11 October 1969, and also between 12 June and 24 July 1970. Most basking sites were on the eastern stream margins, which benefited from increased PM insolation. All observations occurred between 1150 and 1620 h. Typical aquatic basking by *S. odoratus* was only observed on three occasions, although numerous yearling *Graptemys geographica* were observed basking in this manner. Eight *S. odoratus* basked on logs at or near water level. Seven were basking on limbs of small woody saplings or bushes, located at positions from bank-level to heights of more than 1 m. Several turtles basked in sun/shade mosaics created by tree canopy cover. Startled turtles typically plunged from these basking perches into the water below. I was unable to obtain equivalent data for all turtles. However, both genders (N = 7; 3 M, 4 F), and turtles of a wide size range (N = 13; 2.5–7.8 cm PL, 9.4–201 g) basked aerially. All basked alone except one male (8.7 cm CL, 6.6 cm PL, 122 g), which basked with a *Graptemys geographica* and a small *Pseudemys concinna* on a drift log. All *S. odoratus* were near the streams margins and in still pools where the stream bottom was silty mud or silty sand, often with rooted aquatic vegetation. None was observed in areas of stream-swept chert, dolomite, or limestone bottoms. I have no April or May data, and the pools where *Sternotherus* were observed are distant from survey access points and often were not reached in the AM. Also, comparing the Pennsylvania aquatic habitats to those of the North Fork of White River is difficult.

The North Fork of White River is a heavily spring-fed stream of renowned clarity, which flows through a narrow, forested valley. Water temperature data from North Fork collecting sites recorded maximum monthly temperatures of 20°C in June, 22.5°C in July, 22°C in August, 21°C in September and 16°C in October. Corresponding monthly air temperature maximums, measured ca. 0.5 m from the water, were 28°C in June, 28.5°C in July, 29.8°C in August, 29.5°C in September and 21°C in October (Nickerson and Mays 1973. The Hellbenders: North American "Giant Salamanders." Milwaukee Public Museum Publ. Biol. Geol. No. 1. 106 pp.). The mean preferred temperature of *S. odoratus* is 21–

26°C (Hutchison 1979. *In* Harless and Morlock [eds.], Turtles: Perspectives and Research, pp. 207–228. Wiley, New York). Thus, water temperatures in the study area seldom reached the preferred temperatures of this species. These observations would support the hypothesis that the unusual aerial basking activity of this *S. odoratus* population is in response to marginal or non-optimal aquatic temperatures, even during the warmest portion of the annual cycle. However, Manning and Grigg (Copeia 1997. 1997:579–584) showed that basking was not of thermoregulatory significance in *Emydura signata*. One alternative hypothesis would be that the *S. odoratus* in this study are adjusting their basking behavior in response to a low dietary intake of vitamin D3.

I thank C. E. Mays, H. Barton, R. Cooper, and C. Selman for their assistance in the stream surveys, and Gary Ferguson for his comments. Funding was provided by Arkansas State University FRG 511-619 and 511-619 supplement, Max Allen's Zoological Gardens, and the F. L. Ott Research Fund of the Milwaukee Public Museum.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). **NECTIVORY and FLOWER POLLINATION.** Anoles forage mainly on arthropods, but they are also known to take fruit (Lazell 1972. Bull. Mus. Comp. Zool. 143:22–74) and even lap nectar from flowers (Bartlett 1995. Reptiles 2:48–65). While nectivory is relatively rare among lizards, green anoles (*Anolis carolinensis*) have been observed obtaining nectar from hummingbird feeders (Liner 1996. Herpetol. Rev. 27:78), *A. stratulus* was observed lapping nectar from flowers of a euphorb in the British Virgin Islands (Perry and Lazell 1997. Herpetol. Rev. 28:150–151), and *A. conspersus* was observed lapping nectar from orchids on Grand Cayman Island (Echternacht et al. 2000. Herpetol. Rev. 31:173). As a result of nectar foraging, some lizards are also effective plant pollinators (Traveset and Sàez 1997. Oecologia 111:241–248, and references therein). We have regularly observed both male and female green anoles lapping nectar from the flowers of both saw palmettos (*Serenoa repens*) and cabbage palmettos (*Sabal palmetto*). These observations were made during a field study conducted on dredge spoil islands created by the U.S. Army Corps of Engineers along the intracoastal waterway in Mosquito Lagoon, within the boundaries of Canaveral National Seashore (CANA) and Merritt Island National Wildlife Refuge (MINWR), Volusia and Brevard Counties, Florida.

Foraging observations were made during capture-mark-recapture surveys conducted in the summers of 1995 through 1998. Large numbers of insects (mostly Hymenoptera, Diptera, and Coleoptera) congregate on the flower heads of these and other plant species to consume nectar, and green anoles were occasionally observed slowly moving about flower heads foraging for arthropods. In these cases, we documented foraging behaviors for a few minutes before the lizards were captured. During May and June of each year of the study, we observed green anoles consuming nectar (27 observations total), and pollen was found on the rostrum of most of these individuals. Brown anoles (*A. sagrei*) were never observed consuming nectar, a finding consistent with their sit-and-wait foraging strategy.

At this latitude, *Serenoa repens* and *Sabal palmetto* produce flowers throughout spring and summer, and the flowers of *S. repens* are suitable for making honey (Taylor 1992. Florida Wildflowers. Taylor Publ. Co., Dallas, Texas). Furthermore, these two species of plants often make up significant portions of the vegetation of many habitat types in Florida (Myers and Ewel 1990. Ecosystems of Florida. University of Central Florida Press, Orlando, Florida), and the flowering heads are very large, containing thousands of flowers. Nectar could be an important food source, however its relative energetic contribution to a lizard's diet must ultimately depend on season and plant species present. Nectivory was relatively rare in this study, which was conducted over a tiny portion of the geographic range of the green anole. However, these observations further demonstrate that nectivory is a more important anole foraging strategy than previously thought, and that green anoles may play at least a minor role in plant pollination.

We sincerely thank John Stiner (CANA) and Mark Epstein (MINWR) for permission to access the islands, and the University of Central Florida for extensive logistical support.

Submitted by **TODD CAMPBELL**, Department of Ecology and Evolutionary Biology, 569 Dabney Hall, University of Tennessee, Knoxville, Tennessee 37996, USA (e-mail: lizardman@utk.edu), and **CATHERINE BLEAZY**, Division of Natural Sciences, Maryville College, Maryville, Tennessee 37804, USA.

ANOLIS* SP.** and ***GONATODES ALBOGULARIS (Yellow-headed Gecko). **PREDATION.** During a trip to Cuba in the summer of 1999, I witnessed two instances of predation on small lizards by the introduced house sparrow, *Passer domesticus*. In most human inhabited areas, particularly in and around La Habana, I noticed the introduced house sparrow to be very common. These weaver finches eat fruits and insects (Ehrlich et al. 1988. The Birder's Handbook. Simon and Schuster/Fireside Books. New York. 667 pp.) as well as discarded human food. Here I report on lizards as a food item for Cuban house sparrows. On 9 July 1999 in La Lisa, Habana, I observed an adult house sparrow attack a hatchling *Anolis* sp. perching on the side of a fence post. The lizard was very likely *A. porcatus,* as there was a resident adult pair in the vicinity. The lizard was close to ground level, and as the bird approached it tried to escape by climbing up and around the post. After an unsuccessful aerial attack, the bird landed and quickly hopped around the post, jumped, and grabbed the lizard by the head. The lizard was pecked twice and then swiftly swallowed. Three days later (12 July 1999) in a nearby yard, I observed another house sparrow capture and eat a *Gonatodes albogularis*. The bird swooped down and grabbed the lizard from its perch on a cinder block. Once again the bird pecked the lizard before swallowing it. Lizards, particularly anoles and geckos, are commonly encountered in high numbers in and around residential areas throughout the Caribbean. Many of these species or their young are small enough to be preyed upon by opportunistic house sparrows. At the high population densities observed, the house sparrow may be an important factor in Cuban urban lizard ecology.

Zoology, University of California, Berkeley, California 94720-3160, USA; e-mail: culebron@socrates.berkeley.edu.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **ENDOPARASITES**. The Mediterranean gecko, *Hemidactylus turcicus,* is native to the Old World (North Africa, Middle East, southern Europe, etc.) and has been established at many localities in the West Indies, Panama, Mexico, and the southern United States, including southern Arizona, southern California, and southern Nevada (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians: Eastern and Central North America, Houghton Mifflin Company, Boston, Massachusetts. 616 pp.; Saethre and Medica 1993. Herpetol. Rev. 24:154–155). It was first collected in southern Arizona from Tucson in 1970 (Robinson and Romack 1973. J. Herpetol. 7:311–312). There are three reports of helminths from *H. turcicus* from the United States, all from Texas (Pence and Selcer 1988. Copeia 1988:565–572; Riley et al. 1988 J. Parasitol. 74:481–486; McAllister et al. 1993. J. Helm. Soc. Washington 60:280–282). The purpose of this note is to report helminths of *H. turcicus* from Tucson, Arizona.

Thirty-six *Hemidactylus turcicus* (mean SVL = 46.4 mm ± 8.5 SD, range = 26–56 mm) were collected during May and August 1999 at apartment complexes in northwest Tucson (32°16'N, 110°58'W), Pima County, Arizona, USA. Lizards were sacrificed within 24 h of capture. The abdominal cavity was opened and the body cavity, liver, esophagus, stomach, small and large intestines, and lungs were examined for helminths under a dissecting microscope. Helminths were removed and placed in a vial of 70% ethanol for a minimum of 48 h. Nematodes were cleared on a glass slide in undiluted glycerol for examination. Selected cestodes were stained with hematoxylin and mounted on glass slides in balsam for identification. Two species of helminths were found; cysts within lizard peritonea contained larvae of the spirurid nematode *Ascarops strongylina,* and lizard small intestines contained gravid individuals of the cyclophyllidean cestode *Oochoristica macallisteri*. Voucher helminths were deposited in the United States National Parasite Collection: *O. macallisteri,* slide, USNPC 89267; *A. strongylina* (larvae), vial, USNPC 89266. Geckos were deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM 145481–145510; 145514–145518; 145751). Twelve geckos (33%) harbored *O. macallisteri*, and 19 (53%) harbored larvae of *A. strongylina*. Mean intensity (total number of individuals of the parasite species divided by number of infected hosts) was 5.2 ± 8.3 SD for *O. macallisteri* and 5.6 ± 5.7 SD for *A. strongylina*. Mean abundance (total number of individuals of a parasite species in a sample of a host divided by the number of hosts examined) was 2.9 ± 5.0 SD for *O. macallisteri* and 1.7 ± 5.3 SD for *A. strongylina*.

Larvae of *A. strongylina* in cysts were previously reported in *H. turcicus* from Texas (McAllister et al., *op. cit.*). They also were found in *Sceloporus occidentalis* and *Sceloporus vandenburgianus* from California (Goldberg and Bursey 1988. J. Wild. Dis. 24:568–571; Goldberg and Bursey 1989. J. Wild. Dis. 25:630–633). *Ascarops strongylina* is a common stomach parasite of pigs (Suidae) and requires an insect intermediate host for development (Anderson 1992. Nematode Parasites of Vertebrates: Their Development and Transmission. C.A.B. International, Oxon, U.K., 578 pp.). *Hemidactylus turcicus* may serve as a paratenic (transport) host for this helminth, but infection of this gecko appears to be incidental (a by-product of diet) because development of the parasite to adult does not occur. *Oochoristica macallisteri* was described from *Uta stansburiana* collected in Los Angeles County, California (Bursey and Goldberg 1996. Folia Parasitol. 43:293–296). *Hemidactylus turcicus* represents a new host record and Arizona a new locality record for *O. macallisteri*. This is the first record of *A. strongylina* larvae in lizards from Arizona.

Hemidactylus turcicus were collected under permits issued by the Arizona Department of Game and Fish.

MABUYA GUAPORICOLA (Calango-Liso). **NATURAL HISTORY**. *Mabuya guaporicola* occurs in the Cerrado and Pantanal biomes and is known from very few specimens from Rio Guaporé, Mato Grosso state, Brazil (Dunn 1936. Proc. Acad. Nat. Sci. Philadelphia 87:533–557), Barra do Bugres, Mato Grosso state, Brazil (Nascimento et al. 1988. Bol. Mus. Para. Emílio Goeldi, nova sér., Zool., Belém 4:21–66), Cachimbo, Pará state, Brazil (Ávila-Pires 1995. Lizards of Brazilian Amazonia, Zool. Verh. Leiden. 706 pp.), and Departamento Santa Cruz and Departamento Beni, Bolivia (Fugler 1989. Ecología en Bolivia 13:57–75). Virtually nothing is known of the ecology of this species. Herein we provide new locality records and new data on habitat, time of activity, body and environmental temperatures, behavior, reproduction, and diet, and also a description of the color in life of *M. guaporicola* from the Brazilian Cerrado.

Lizards were collected at Ilha do Bananal, Santa Terezinha, Mato Grosso state, (10°26'S, 50°35'W) (7 individuals, April 1999), Cachimbo, Pará state (3 individuals, March 1995), and Brasília, Distrito Federal (15°47'S, 47°55'W) (1 individual, September

TABLE 1. Diet of *Mabuya guaporicola* (N = 10; f = number of stomachs, n = number of items).

Prey Item	f	f%	n	n%
Araneae	1	10	1	10
Coleoptera	5	50	5	50
Diptera	1	10	1	10
Formicidae	1	10	1	10
Grillidae	1	10	1	10
Hemiptera	3	30	3	30
Unidentified insects	1	10	1	10
Orthoptera	5	50	5	50
Termitidae	2	20	4	40

1991). At Ilha do Bananal specimens were collected in "campo de murunduns," a seasonally flooded grassland with sparse mounds covered with small trees, and in "campo sujo," a grassland with very sparse schrubs. At Cachimbo, lizards were collected in "campo sujo" over sandy soils. No habitat data are available for the Brasília specimen. Overall, it seems that *M. guaporicola* prefers more open physiognomies of Cerrado.

Lizards at Ilha do Bananal (4) and Cachimbo (3) were collected (1100 to 1200 h) while basking. Three individuals at Ilha do Bananal were collected in pitfall traps; all the others were collected by hand. Cloacal temperatures (N = 4) averaged 35.05°C ± 0.85. Mean environmental temperatures were as follows: substrate 32.25°C ± 0.85, air at 5 cm above the substrate 30.75°C ± 1.14, and air at chest height 29.80°C ± 0.98. Therefore, *M. guaporicola* is apparently a heliophyllic species. After being approached, lizards moved quickly amidst grasses by rapid lateral undulation of the body and tail, seeking refuge in the leaf litter beneath shrubs. Limbs are apparently adpressed against the body during rapid locomotion.

With the exception of a male from Cachimbo (SVL = 37 mm), all individuals were reproductive. Clutch size (N = 4) averaged 4.25 ± 0.50, range 4 to 5. The smallest reproductive male measured 63 mm SVL, whereas the smallest reproductive female measured 43 mm SVL. The largest male measured 70 mm SVL and the largest female measured 82 mm SVL. Hence, *M. guaporicola* is apparently sexually dimorphic, with females attaining a larger body size than males, and females apparently attain sexual maturity at an early age, as seems to characterize several neotropical congeneric species (Vrcibradic and Rocha 1998. Copeia 1998:612–619; Vitt and Blackburn 1991. Copeia 1991:916–927).

Mabuya guaporicola has a relatively diverse diet, the most important prey items being coleopterans, orthopterans, hemipterans, and termites (Table 1). Color in fixative was described by Ávila-Pires (*op. cit.*). In life, the dorsum is light brown with three narrow, dark brown longitudinal stripes (sometimes interrupted) from the nape to the tip of the tail. The flanks are marked with two longitudinal dark-brown stripes separated by a light stripe; upper one broader, from the snout to the tip of the tail; lower one from the commissure of the mouth to the tip of the tail. Limbs are light-brown from above, with irregular dark spots. Gular region, chest, belly, and ventral part of limbs are immaculate.

Submitted by **DANIEL O. MESQUITA, AYRTON K. PÉRES, JR., GUSTAVO H. C. VIEIRA**, and **GUARINO R. COLLI**, Departamento de Zoologia, Universidade de Brasília, 70910-900 Brasília-DF, Brazil; e-mail (DOM): danmesq@unb.br.

MICRABLEPHARUS ATTICOLUS (NCN). **NATURAL HISTORY.** *Micrablepharus atticolus* is an endemic of the Cerrado biome in South America and was named for observations suggesting an association with nests of leaf-cutter ants, genus *Atta*, in which the lizards seek refuge (Vitt 1991. J. Herpetol. 25:79–90; Rodrigues 1996. Herpetologica 52:535–541). These observations led Rodrigues (*op. cit.*) to hypothesize that the advanced eyelid condition in *M. atticolus* (complete suture between upper and lower eyelids, compared to presence of eyelid in *M. maximiliani*) could be related to the habit of burrowing in sand at the base of ant nests. Natural history data on the species, based on few specimens from Alto Araguaia, Mato Grosso, were provided by Vitt (*op. cit.*). Herein we present data on microhabitat, body and environmental temperatures, reproduction, and diet of *M. atticolus* from two Cerrado localities. We collected 16 individuals at Chapada dos Guimarães, Mato Grosso state, Brazil (15°26'S, 55°45'W), during September and October 1988. In April 1999 we further collected, by manual capture and using pitfall traps, 24 individuals of *M. atticolus* at Parque Nacional do Araguaia, Ilha do Bananal, Santa Terezinha, Tocantins state, Brazil (10°26'S, 50°35'W).

TABLE 1. Diet composition of 15 *Micrablepharus atticolus* (N = number of stomachs, n = number of prey, v = volume of prey in mm^3).

Prey Item	N	f%	n	n%	v	v%
Araneae	2	13.33	2	8	18.83	7.69
Insect larvae	1	6.67	1	4	69.33	28.32
Homoptera	5	33.33	5	20	64.14	26.20
Lepidoptera	1	6.67	1	4	27.82	11.36
Unidentified insects	5	33.33	9	36		
Orthoptera	5	33.33	7	28	64.72	26.43

At Chapada dos Guimarães lizards were collected in low cerrado over sandy soils. At Ilha do Bananal specimens were collected in "campo de murunduns," a seasonally flooded grassland with sparse mounds covered with small trees, and in "campo sujo," a grassland with sparse shrubs. None of the lizards were associated with nests of *Atta*, which were not common at the study sites. Hence, it seems that *M. atticolus* prefers open physiognomies of Cerrado and uses nests of *Atta* opportunistically. Temperature data of two individuals were as follows: cloacal temperatures = 35.0°C and 34.2°C; substrate = 34.0°C and 31.2°C; air at 5 cm above the substrate = 30.4°C and 30.8°C, and air at chest height = 29.6°C and 29.8°C, suggesting that *M. atticolus* is a heliophyllic species.

With the exception of one female and three males, all individuals were reproductive. Clutch size (N = 13), based on counts of vitellogenic follicles or oviductal eggs, averaged 1.9 ± 0.3 (range 1–2; one female presented a single vitellogenic follicle). Three females presented vitellogenic follicles and oviductal eggs, indicating multiple clutches during the reproductive season. The smallest reproductive male, based on the presence of enlarged testes and epididimydes, measured 34 mm SVL, whereas the smallest reproductive female measured 26 mm SVL. No difference was observed in mean SVL between the sexes (adult individuals only; males: 37.3 ± 1.9, N = 27; females: 38.8 ± 4.6, N = 13; $F = 2.07$, $p = 0.16$). The largest male measured 41 mm SVL and the largest female measured 43 mm SVL. Hence, there is no sexual dimorphism in SVL in *M. atticolus* and females seemingly attain sexual maturity at an early age.

Micrablepharus atticolus has a relatively diverse diet (Table 1). Most lizards ingested homopterans, orthopterans, and unidentified insects. Numerically, unidentified insects, orthopterans, and homopterans prevailed, while volumetrically, insect larvae, orthopterans, and homopterans were most important.

PHRYNOSOMA DITMARSI (Rock Horned Lizard). **ENDOPARASITES.** The rock horned lizard, *Phrynosoma ditmarsi*, is endemic to Sonora, Mexico (Hodges 1995. Cat. Amer. Amph. Rept. 614.1–614.3). It has been reported to harbor the nematode *Skrjabinoptera phrynosoma* (Roth 1971. J. Arizona Acad. Sci. 6:278–281). The purpose of this note is to report *P. ditmarsi* as a host of the cestode *Oochoristica scelopori*. Three adult *P. ditmarsi* from the herpetology collection of the University of Arizona, Tucson, (UAZ) were examined (UAZ 32340 collected September 1970, 2 km NE Mina Alecrán; UAZ 32357, September 1970, Rancho Alecrán; UAZ 39540, July 1974, Cerro de la Palma). The body cavity was opened and the esophagus, stomach, small intestine, large intestine, coelom, and liver were searched for helminths using a dissecting microscope. One cestode was present in the small intestine of UAZ 39540. It was dehydrated, cleared, stained in hematoxylin, mounted in balsam, examined under a compound microscope and identified as an immature *O. scelopori*. No endoparasites were found in UAZ 32357. Among the ingesta in the stomach of UAZ 32340 were eleven third-stage nematode larvae and one acanthocephalan larva. These specimens were placed on a glass slide in a drop of glycerol, allowed to clear, and identified with the aid of a compound microscope. The nematode larvae were assigned to the genus *Physaloptera* and the larval acanthocephalan was assigned to the family Oligacanthorhynchidae. All specimens were deposited in the United States National Parasite Collection: *Oochoristica scelopori* USNPC 89270; physalopteran larvae USNPC 89268; oligacanthorhynchid larva USNPC 89269.

Phrynosoma ditmarsi represents a new host record for *O. scelopori*. This is the first record of *O. scelopori* from the genus *Phrynosoma*. Other horned lizards, namely, *Phrynosoma braconnieri, P. cornutum, P. solare*, and *P. taurus* have been reported to harbor a different cestode, *Diochetos phrynosomatis* (Goldberg and Bursey 1991. Southwest. Nat. 36:365–368; Goldberg et al. 1993. J. Helm. Soc. Washington 60:234–238). *Oochoristica scelopori* has been reported from 15 species of North American lizards, primarily sceloporines (Goldberg et al. 1996. Great Basin Nat. 56:180–182).

Species of *Physaloptera*, as well as species of the Acanthocephala require an insect intermediate host (Cheng 1986. General Parasitology. 2nd Ed., Academic Press, Orlando, Florida. 827 pp.). Any insectivore could be expected to have representatives of these species in the ingesta. Larval physalopterans (and absence of adults) have been reported from the digestive tracts of 22 species of anurans and 15 species of lizards (Goldberg et al. 1993. Bull. S. California Acad. Sci. 92:43–51). Encysted cystacanths have been found in spceies of *Cnemidophorus* and *Sceloporus* (Goldberg et al. 1995. J. Helm. Soc. Washington 62:188–196). This report of physalopteran larvae and the acanthocephalan cystacanth must be considered an incidental occurrence, a byproduct of diet, until adult individuals of a species of *Physaloptera* and encysted or mature acanthocephalans are reported from *P. ditmarsi*.

We thank Charles H. Lowe (The University of Arizona) for permission to examine *P. ditmarsi*.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA, and **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA.

PHRYNOSOMA MODESTUM (Roundtailed Horned Lizard). **NOCTURNAL NEST-DIGGING and OVIPOSITION.** On 20 July 1997 a gravid female (mass 13.4 g; SVL 59 mm) *Phrynosoma modestum* was collected 0.5 km north of Cave Creek (Foothills Road to San Simon) near Portal (elevation 1400 m), San Simon Valley, Cochise County, Arizona, USA. The lizard was fitted with a Holohil BD-2A radiotransmitter (0.62 g; 148 KHz; pulse 0.6; whip antenna 15.5 cm) and released 22 July (1400 h) at a study site 4.4 km to the southeast. The lizard was relocated once or, usually, twice daily for the next eight days (15 times, day and night). After dark (2150 h) on 22 July it was observed to be digging, its body just inside a slanting tunnel, in moist sandy soil (rain had fallen on the site 20 and 21 July) at a vegetation-free location, air temperature (AT) 24°C. The following morning, 23 July at 0530 h, the lizard was located sleeping (eyes closed) on the dig site, AT 20°C. The excavated hole had been filled in and the area surrounding the hole was clearly disturbed (scratched). Fifteen minutes later the lizard had shifted to a new position, eyes were closed. The sun had risen above the horizon but was not shining on the lizard. Later that day, 1400 h (AT 35°C), the lizard had moved 49 m away and never returned to the site. The scraped area around the nest was larger than it had been in the morning and the hole was completely filled in. That evening, 2115 h, the nest was dug up and 12 eggs (average clutch size for *P. modestum* is 11.2 ± 9.7, range 7–18: Howard 1974. J. Arizona Acad. Sci. 9:108–116) located at 7–8 cm depth were removed. The female was found dead on 30 July, 1440 h, near an active ant nest. These observations suggest that nest digging began late in the day or early in the evening and continued well into the evening, that the egg clutch was laid at night and was mostly covered by morning, and that the finishing of nest-hiding soil arrangement was completed the following morning before the site was abandoned.

Three female *P. solare* have been seen digging at deep nests (35 cm) during the early morning, 0730–0800 h, (suggesting excavation the night before), with oviposition and nest completion by two lizards occurring during the subsequent day or night (Van Devender and Howard 1973. Herpetologica 29:238–239). A captive *P. cornutum* female (mass 82.0 g; SVL 98 mm) captured 23 June 1991 and maintained in an outdoor enclosure at the Southwestern Research Station was seen excavating a nest in the evening on 1 July 1991 (pers. obs.) after 2.3 cm rain fell on 30 June. At 0430 h the following morning, she was observed in the entry hole facing outward, apparently laying her clutch of eggs, and by 1100 h the nest with eggs was completely covered. She remained near

the nest site until at least 1500 h. Both diurnal (N = 3: Hewett 1937. Copeia 1937:234; Ramsey 1956. Herpetologica 12:239–240) and nocturnal (crepuscularly initiated) nestings (N = 6: Edwards 1896. Zool. Anz. 19:108–111; Cahn 1926. Am. Nat. 60:546–551) have been recorded for *P. cornutum* under varied conditions. Nocturnal, summer nesting at the onset of the monsoonal rainy season may allow females of some species of horned lizards to 1) avoid attracting diurnal predators with their digging activities at exposed sites, 2) avoid possible high daytime surface temperatures that might cause them to suspend activity before completion of nesting, 3) dig more easily in moistened soil with fewer roots, and 4) provide their eggs with an incubation site that has initial high moisture and that will receive maximal solar radiation due to the lack of vegetative shading.

SCELOPORUS JARROVII (Yarrow's Spiny Lizard). **OCULAR SINUS BLEEDING.** On 28 August 1999 an adult male (mass 20.8 g; SVL 85 mm) *Sceloporus jarrovii* was noosed at 1035 h from a rock along East Turkey Creek, Chiricahua Mountains, elevation 1830 m, 2.5 km upstream from Paradise, Cochise County, Arizona, USA. While the noose-string was being removed, taking ca. 1 min, a large drop of bright-red fluid was noted, split on the supraocular scales above the right eye and on the mid-edge of the open upper eyelid. Examination of the eye with a 10x hand lens revealed a reddish tinge, which was no longer apparent two hours later. Apparently the fluid was the lizard's blood, expelled from the vascular system due to increased pressure in the sinus orbitalis and rupture(s) of one or more capillaries. The position of the blood above the eye suggests possible upward ejection, perhaps through the tear duct as postulated in the blood-squirting species of horned lizards (*Phrynosoma coronatum*, Burleson 1942. Copeia 1942:246–248; and *P. cornutum*, Middendorf and Sherbrooke 1992. Copeia 1992:519–527). Although autohemorrahaging is apparently rare in reptiles (Smith et al. 1993. Herpetol. Rev. 24:130–131; Greene 1988. *In* C. Gans and R. B. Huey [eds.], Biology of the Reptilia, vol. 16, pp. 1–152), observations of ocular-sinus autohemorrahaging have been made in snakes (Smith et al., *loc. cit.*) and in another species of iguanid lizard, *Urosaurus ornatus* (Mahrt 1996. Herpetol. Rev. 27:21–22).

An antipredator defensive role has been suggested for ocular blood squirting by some horned lizards (Middendorf and Sherbrooke, *loc. cit.*). Delivery of distasteful compounds circulating in the blood of these lizards onto the oral or other membranes of a predator apparently is a more effective defense than their release as a result of predator inflicted wounds. The rare occurrence of ocular-sinus bleeding by lizards outside the *Phrynosoma* clade suggests a precursor character, ability to exhibit occular-sinus bleeding during tactile trauma, that could have undergone positive natural selection once horned lizards incorporated chemicals into their blood that were distasteful to some predators.

TARENTOLA (=MAKARIOGECKO) DELALANDII (Delalande's Gecko). **MAXIMUM SIZE.** *Tarentola delalandii* Dumeril and Bibron 1836 is endemic to the Canary Islands (Spain), where it is known only from the islands of La Palma and Tenerife, and from the Roques of Anaga and Garachico, near Tenerife Island. At present, most of the details concerning its biology remain unknown and few studies have addressed its morphology (Joger 1984. Cour. Forsh. Inst. Senckenberg 71:91–111; Joger and Bischoff 1983. Bonn. Zool. Beitr. 34:459–468). This species has previously been considered a small- to medium-sized gecko, reaching a maximum SVL of 70 mm (Salvador 1985. Guía de Campo de los Anfibios y Reptiles de la Península Ibérica, Islas Baleares y Canarias. S. García, León. 212+XLIII pp; Barbadillo 1987. La Guía de Incafo de los Anfibios y Reptiles de la Península Ibérica, Islas Baleares y Canarias. Incafo, Madrid. 694 pp.), thus being much smaller than the congeneric *T. mauritanica*. On 23 February 1998, on the island of Tenerife, we captured, measured, and photographed a male *T. delalandii* that measured 84 mm SVL (mass = 18.5 g). The specimen was then released. This size greatly exceeds the maximum known SVL for this species and is comparable to the maximum SVL reached by *T. mauritanica* (86 mm, Martínez-Rica 1974. Publ. Cent. Piren. Biol. Exp. 5:1–291). This observation indicates that the two species can actually reach similar sizes.

VARANUS SALVATOR (Water Monitor). **NESTING BEHAVIOR**. During a study of the nesting behavior of the Nicobar Megapode (*Megapodius nicobariensis*) on Great Nicobar Island (6°45'–7°15'N, 93°38'–93°55'E), I observed nesting of the water monitor, *Varanus salvator*. Unlike most birds, megapodes do not brood their eggs, but instead bury them in large mounds of sand, soil, and organic matter. The eggs are warmed by the decomposition of organic matter and the adult bird attends the mound, adding or removing sand to maintain the proper incubation temperature (Sankaran and Sivakumar 1999. Zoologische Verhandelingen 327:75–90). This study occurred from December 1995 to May 1998. During the peak megapode nesting period (February through May) water monitors were frequently seen at nest mounds, often while adult megapodes were present. These monitors are the primary predators of megapode eggs on Great Nicobar Island but are not known to prey on adult megapodes.

While the main breeding season of *V. salvator* occurs in October and November, breeding has been known to occur throughout the year (Horn and Visser 1989. Int. Zool Ybk. 12:140–150). On four occasions, *V. salvator* were observed nesting in the nest mound of the Nicobar megapode. One of these clutches (11 eggs) was immediately unearthed and reburied with a thermal sensing probe in the ground near the nest (this clutch became our control). The other three (9, 10, and 11 eggs) were left within the megapode nest mounds. Maximum temperature of the control clutch was 28°C, while the megapode nest mounds averaged 32.5°C. All clutches hatched successfully. The control clutch hatched in 305 days, while the nest mound clutches hatched after an average of

265 days. Previous studies of incubation period of *V. salvator* reported periods varying from 222 to 327 days (Andrews and Gaulke 1990. Hamadryad 15:1–5; Horn and Visser, *loc.cit.*). The shorter incubation period for the nest mound clutches when compared to the control clutch was presumably due to the increased temperature within the mounds.

SERPENTES

AGKISTRODON PISCIVORUS (Cottonmouth). **DIET**. On 26 March 1984 we found an adult female *Agkistrodon piscivorus* (124 cm total length) consuming a litter of swamp rabbits (*Sylvilagus aquaticus*). The young rabbits were in a nest among dense vegetation along Bayou Fountain, ca. 2.5 km SE of the intersection of Siegen Lane and Highland Road, East Baton Rouge Parish, Louisiana, USA. The cottonmouth was collected and later deposited in the Campbell Museum, Clemson University, Clemson, South Carolina (CUSC 1825). The snake was ingesting one rabbit, and a second rabbit was found dead in the nest. The latter probably had been envenomated a short while earlier. We dissected the snake and recovered a third rabbit from the stomach. The rabbits were estimated to be about two weeks old and each was ca. 15 cm long. Cottonmouths are generalist predators known to consume a variety of mammalian prey, but our observation constitutes the first record of swamp rabbit predation (Ernst 1992. Venomous Reptiles of North America. Smithsonian Institution Press, Washington, D.C. 236 pp.).

We thank Mike Leggio for field assistance, Travis Crabtree for reviewing a draft of this manuscript, and Stanlee Miller (Campbell Museum) for assistance with specimen preparation.

ALSOPHIS VUDII (Bahamian Brown Racer). **OVERWATER DISPERSAL**. Anecdotal accounts exist of snakes being encountered in the marine waters of the Bahamas. Some of these accounts probably stem from the morphological similarities of eels in the genus *Myrichthys* to colubrid snakes. Another possible explanation may be overwater movements of *Alsophis*, *Epicrates*, or *Tropidophis* throughout the shallow Bahamian seas of the Great Bahama Bank. On 8 March 1998, I witnessed an *Alsophis vudii* emerging from the surf onto the eastern beach of Alligator Cay, Exuma Cays Land and Sea Park, Bahamas (24°23'N, 76°38'W). The snake exited the sea at 1535 h and remained basking on the beach rock for 20 min before retreating to the karst limestone ridge adjacent to the beach. This species has not been reported from this cay (Franz et al. 1993. Carib. J. Sci. 29:165–173) and is most likely a random migrant. The closest neighboring cay is 100 m to the north and separated by a channel of flowing water that coincides with the tides. *Alsophis* inhabits beaches and coastal mangroves (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. Univ. Florida Press, Gainesville, Florida. 720 pp.); however, this is the first documented account of this species taking to the sea and colonizing an island. This event has biogeographic implications and may offer insight to historical and present reptile distributions in the Bahamas.

BOA CONSTRICTOR (Boa Constrictor). **DIET**. *Boa constrictor* diets include a variety of lizards, birds, and mammals (Greene 1983. *In* Janzen [ed.], Costa Rican Natural History, pp. 380–383. University of Chicago Press, Chicago, Illinois). Previous accounts of avian prey items from stomachs of individual *B. constrictor* include an antbird (Formicariidae), a blue-gray tanager (*Thraupis episcopus*, Thraupidae), and an orange-billed sparrow (*Arremon aurantiirostris*, Emberizidae) (Beebe 1946. Zoologica. 31:11–52; Greene 1983, *op. cit.*; Guyer and Donnelly, unpubl.). Here we report an additional avian prey item; a bright-rumped attila (*Attila spadiceus*, Tyrannidae; 39.5 g), palped from a immature female *B. constrictor* (SVL 76 cm, 240 g without prey) on 14 July 1999 at 2100 h at the La Selva Biological Station, Heredia Province, Costa Rica (Fig. 1). This snake was collected about 10 m above ground in a *Pentaclethra macroloba* adjacent to the main suspension bridge over the Rio Puerto Viejo. The snake was released at the point of capture after data were collected.

The birds that have so far been recorded in the diet of *Boa constrictor* occupy diverse strata in the forest, ranging from the ground to the canopy (Stiles and Skutch. 1989. A Guide to the Birds of Costa Rica. Cornell Univ. Press, Ithaca, New York. 511 pp.). This suggests that adult and juvenile *B. constrictor* feed on avian prey throughout the arboreal strata. These snakes may affect important forest processes by consuming key predators of arthropods and dispersers of seeds.

We thank the Organization for Tropical Studies for the opportunity to collect these data.

BOIGA IRREGULARIS (Brown Tree Snake). **PREDATION**. *Boiga irregularis* is an arboreal snake native to Australia and Papua New Guinea with introduced populations on Guam, Saipan, and other islands of the mid-Pacific region. We are unaware of any reports of predators on *B. irregularis* in its native range. We present three instances of predation on *B. irregularis* by the red-bellied black snake (*Pseudechis porphyriacus*) and the cane toad (*Bufo marinus*).

In April 1992, we were feeding chickens in Babinda, Queensland (17°20.50'S, 145°55.54'E), and discovered a 1.6 m total length (TL) red-bellied black snake attempting to capture a similarly-sized brown tree snake in the rafters of the aviary. The red-bellied black snake climbed into the rafters, caught the brown tree snake, and consumed it in ca. three hours. Photographs of the event were taken.

On 3 March 1999 at 1745 h, we examined the stomach contents of a road-killed red-bellied black snake (ca. 1.5 m TL) on a paved highway on the outskirts of Babinda. The snake contained a brown tree snake (ca. 0.8 m TL). No other food items were discovered in the snake's digestive tract.

We also observed a cane toad (*Bufo marinus*) catch and consume a neonate (ca. 50 cm TL) brown tree snake. On 25 May 1998 at 1130 h in a banana plantation outside Babinda, Queensland (17°27.45'S, 145°52.16'E), a brown tree snake fell out of a bunch of bananas during harvest. Brown tree snakes are commonly found in banana bunches by plantation workers in this area. Seconds after the snake fell to the ground, a large *B. marinus* came from under a banana leaf and swallowed the neonate. No specimens were collected from any of the events.

An Australian-American Fulbright Grant and the Jack Berryman Institute for Wildlife Damage Management, Utah State University, provided funding for research of brown tree snake natural history in Australia. Joan Whittier from the Department of Anatomical Sciences, University of Queensland, provided additional support for the project while in Australia.

CROTALUS LEPIDUS KLAUBERI (Banded Rock Rattlesnake). **CAUDAL LURING**. Caudal luring has been reported for a wide variety of crotalines, a handful of viperines, three boids, and one elapid (Strimple 1992. Greater Cincinnati Herpetol. Soc. Contrib. Herpetol. 49–54), and more recently in several colubrids (Sazima 1993. Copeia 1993:222–226; Leal and Thomas 1994. J. Herpetol. 28:126–128; Tiebout 1997. J. Herpetol. 31:290–292). However, the vast majority of observations have been made on captives and observations of luring in the wild are limited to three species (Strimple 1992, *op. cit.*). While caudal luring has been described in captive *Crotalus lepidus* (Kauffeld 1943. Am. Midl. Nat. 29:607–614), we report the first observation of this behavior in the field. Caudal luring has been defined as "the waving or wriggling of a conspicuous tail by an otherwise cryptically colored snake, thereby attracting small animals which attempt to feed on the worm-like or caterpillar-like tail but themselves become prey when they come within striking distance of the snake" (Heatwole and Davison 1976. Herpetologica 32:332–336). This definition requires that prey are attracted to the wriggling tail, a distinction supported by Strimple (1992, *op. cit.*) who suggests the term "caudal-luring–like behavior" be used for observations of tail wriggling in the absence of prey or prey attraction.

On 10 September 1999 at ca. 1013 h one of us (BLS) discovered a neonatal *C. l. klauberi* loosely coiled atop a large (1 x 0.75 m) rock near the upper edge of a steep (35°) talus slide in the Chiricahua Mountains, Cochise Co., Arizona, USA. We assume this specimen was probably less than eight weeks old based on the snake's size, the fact that it possessed only a button, and the phenology of parturition in this species. The snake did not visibly react to the observer's presence 3 m behind it. After sitting motionless for 5 min while being silently observed, the snake raised its tail ca. 1 cm above the dorsum and began undulating it in continuous waves at a frequency of 60–80 cycles per minute. The neon yellow tail was fully exposed ca. 1 cm behind and to the side of the head. The behavior continued uninterrupted for at least 5 min. Cessation of the behavior was concurrent with the appearance of full sun from behind clouds. About 15 sec later the snake slowly crawled to cover.

In the Madrean Archipelago, *C. l. klauberi* diet consists chiefly of *Sceloporus jarrovii* (Holycross, unpubl. data), a diurnal lizard that is especially abundant in talus. Although *S. jarrovii* were not observed in the immediate vicinity (3 m) of the neonatal rattlesnake, numerous individuals were observed throughout the talus prior to and after the observation. The observer did not consciously look for lizards while he watched the snake lure, so it is possible that the snake was luring a specific prey item that the observer did not notice. Alternatively, as suggested by Chiszar et al. (1990. J. Herpetol. 24:253–260), the snake may have been using its tail as a "probe" to lure undetected prey in a microenvironment where prey are reasonably abundant. Since we cannot document attraction of prey to the tail, strict application of the definitions cited above would prohibit interpreting the observed behavior as caudal luring. Nevertheless, we find that the context of this observation strongly suggests the snake was using its tail as a lure to attract prey. If the behavior is an adaptation for misdirecting strikes by potential predators, the placement of the tail over the body seems counterproductive. If it is displacement behavior, it is probably maladaptive in this context where it might attract the attention of a potential predator.

Submitted by **BRYAN L. STARRETT**, Herpetology Section, South Carolina Aquarium, 57 Hasell Street, Charleston, South Carolina 29401, USA (e-mail: bvipers@aol.com), and **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA (e-mail: holycow@asu.edu).

CROTALUS WILLARDI OBSCURUS (New Mexico Ridgenose Rattlesnake). **CAUDAL DICHROMATISM.** *Crotalus willardi willardi* exhibit black, gray striped, and, rarely, yellow tails at birth. Martin (1975. Bull. Maryland Herpetol. Soc. 11:64–65) noted that seven neonates born to a female collected from the Santa Rita Mountains of Arizona all had yellow tails. Martin (1975. Bull. Maryland Herpetol. Soc. 11:187–189) later described another litter from Santa Rita parents; two of these had yellow tails while four had gray striped tails. However, eight *C. w. willardi* (two unrelated litters) born to parents from the Huachuca Mountains (Arizona) did not demonstrate yellow tails at birth, but instead had "dark tails" (Quinn 1977. Bull. Maryland Herpetol. Soc. 13:11; Tryon 1978. Bull. Maryland Herpetol. Soc. 14:83–88). Likewise, yellow tails were absent in three complete litters (17 neonates) and an additional 10 neonates observed by Fred Wilson (pers. comm.) in the Huachuca Mountains. Wilson described these tails as darkly striped. Finally, Martin (1976. Bull. Maryland Herpetol. Soc. 12:126–128) reported a litter of nine Animas Mountain (New Mexico) *C. w. obscurus* that had "mostly black colored tails" but had yellow pigment on the upper and lower labials, rostral, and mental scales.

Herein I report the occurrence of both yellow and black tails in a single litter of *C. w. obscurus*. On 2 August 1998 a 489 mm SVL *C. w. obscurus* was captured in the Peloncillo Mountains, New Mexico. Palpation revealed eight embryos. On 13 August 1998 at 0800 h her mass was 138 g. At 1551 h eight neonates were discovered in the container housing the female; three still partially encased in embryonic sacs. Parturition was complete by 1730 h. The female's mass was 78 g at 1905 h. Litter mass represented 54.5% of the female's postpartum mass. Litter mass and mass of expelled fluids/tissues combined represented 76.9% of the female's postpartum mass. Neonate morphometrics are within previously reported ranges (mean ± SD: 158.9 ± 2.2 mm SVL, 5.3 ± 0.3 g). At birth, six of the neonates had yellow tails, while the remaining two had dark tails. After shedding, the tails of the former were brighter yellow while the latter two had nearly solid black tails. All specimens had very faintly striped tails. All of these neonates had yellowish facial markings as described by Martin (1976, *op. cit.*). All eight offspring and the mother were released at point of capture.

Although caudal luring has not been formally reported in *C. willardi*, Schuett et al. (1984. Anim. Behav. 32:624–629), Greene (1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 107–118. Selva, Tyler, Texas), and Strimple (1992. Greater Cincinnati Herpetol. Soc. Contrib. Herpetol., pp. 49–54) all cite an unpublished observation by Bern Tryon as a personal communication. Most juvenile vipers with brightly colored tails use the tail to lure prey (Strimple, *op. cit.*). Those that have not yet been observed luring, are expected to do so, or be descendants of snakes that did so (Greene, *op. cit.*). It is generally assumed that bright coloration is an adaptation that renders the tail more attractive to prey such as diurnal lizards that have excellent color vision (e.g., Fleishman et al. 1997. J. Comp. Phys. A 181:446–460). In this context it seems probable that juvenile *C. w. obscurus* caudal lure with their sometimes brightly colored tails for *Sceloporus jarrovii*, their primary prey (Holycross, unpubl. data). Interestingly, while vicariance has led to the evolution of manifest differences in ground color and facial pattern between *C. w. obscurus* and *C. w. willardi*, yellow tails have been preserved in both at low frequency, despite small population sizes and potential for bottlenecks in some isolates. *Crotalus willardi* or other species with polymorphic tail coloration (e.g., some *Bothrops* spp. where the trait is sex-linked) may be ideal species for addressing questions related to the function and microevolution of brightly colored tails in juvenile pitvipers. On a broader scale, it is unclear whether bright tail coloration is homoplasious or homologous within pitvipers. Caudal luring is widespread among pitvipers and may be a homology (or "latent homology") preserved by the clade's widespread dependence on "sit and wait" foraging strategies (Greene, *op. cit.*). Caudal luring may then provide a context for repeated independent evolution of brightly colored tails within Crotalinae.

Submitted by **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA (e-mail: holycow@asu.edu).

HAPSIDOPHRYS SMARAGDINUS (Emerald Snake), ***PHILOTHAMNUS IRREGULARIS*** (NCN), ***PHILOTHAMNUS HETERODERMUS*** (NCN), ***DASYPELTIS* SP.** (Egg-Eating Snake), ***AFRONATRIX ANOSCOPUS*** (Brown Water Snake), ***GRAYIA SMYTHII*** (Smyth's Water Snake), ***NATRICITERES VARIEGATUS*** (NCN), ***BOAEDON LINEATUS*** (House Snake), and ***APARALLACTUS NIGER*** (Centipede-Eater). **CAUDAL PREHENSION.** Between January 1986 and June 1989, I collected several live colubrid snakes in Liberia, western Africa. These included five *Hapsidophrys smaragdinus* (total lengths = 38 cm, 73 cm, 84 cm, 87 cm, 98 cm), five *Philothamnus irregularis* (TL = 56 cm, 66 cm, 76 cm, 90 cm, 91 cm), one *Philothamnus heterodermus* (TL = 58 cm), one *Dasypeltis* sp. (TL = 61 cm), ten *Afronatrix anoscopus* (TL = 23 cm, 23 cm, 24 cm, 25 cm, 28 cm, 40.5 cm, 42 cm, 52 cm, 53 cm, 54 cm), two *Grayia smythii* (TL = 112 cm, 130 cm), one *Natriciteres variegatus* (TL = 35 cm), four *Boaedon lineatus* (TL = 35 cm, 65 cm, and two adults of unrecorded length), and three *Aparallactus niger* (TL = 44 cm, 48 cm, 57 cm). In these snakes, I tested for caudal prehensile ability by running a finger along the tail. If the snake's tail responded to this by seizing the finger, I concluded that the tail was prehensile. If the tail did not seize the finger after four trials, I concluded that the tail was not prehensile. All specimens were handled repeatedly, and in no case did subsequent handling falsify these conclusions.

Strong prehensile ability (ability to grip tightly) was found in *H. smaragdinus*, *P. heterodermus*, *P. irregularis*, *A. anoscopus*, *G. smythii*, *Dasypeltis* sp., *A. anoscopus*, and *G. smythii*. Weak prehensile ability (ability to grip, but not tightly) was found in *N. variegatus*. In all specimens of all nine species, the finger was seized on the first trial. A review of the literature (Schmidt 1923. Bull. Am. Mus. Nat. Hist. 49:1–145; Villiers 1950. IFAN Initiations Africaines 2:1–148; Broadley 1957. Afr. Wild Life 11:53–55; Doucet 1963. Acta Tropica 20:201–340; Cansdale 1971. West African Snakes. Longman Group Ltd, Essex, United Kingdom, 74 pp.; Dunger 1971. The Nigerian Field 36:21–38; Dunger 1973. The Nigerian Field 38:158–180; Pitman 1974. A Guide to the Snakes of Uganda, Revised Edition, Wheldon and Wesley, Ltd, Codicote, England, 290 pp.; Marais 1992. A Complete Guide to the Snakes of Southern Africa, Krieger Publishing Company,

Malabar, Florida, 208 pp.; Branch 1998. Field Guide to the Snakes and other Reptiles of Southern Africa, Ralph Curtis Books, Sanibel Island, Florida, 399 pp.) revealed that caudal prehension in members of all the genera examined here is heretofore unreported. The only exception to this is a statement by Pitman (*op. cit.*, p. 96) that the tail of *P. semivariegatus* is "highly prehensile."

The discovery of prehensile tails in arboreal species (*H. smaragdinus*, *P. heterodermus*, *P. irregularis*, *Dasypeltis* sp.) is not surprising. These snakes use their tails to grip branches during climbing, thereby gaining more stability (pers. obs.).

Afronatrix anoscopus is an aquatic species that uses caudal prehension to anchor itself during underwater ambush foraging (pers. obs.). *Afronatrix anoscopus* grips a submerged rock or stick with its tail while awaiting its prey. When a fish, frog, or tadpole comes within striking range, the snake shoots its head toward the prey item, seizes it with its mouth, and commences to swallow, all the while maintaining a caudal grip upon its anchor. If the snake's strike misses, the snake often remains anchored to the same object and awaits the next prey item.

Of all the species examined here, the strongest caudal grip (as measured by the feeling of pressure upon the researcher's fingers and arms) is exhibited by *Grayia smythii*. I once wrapped the tail of a 1.3-m individual around a tree branch, and let the snake hang with no other support. The snake tried repeatedly to pull the rest of its body up onto the branch, but was unable to do so, although it maintained its caudal grip with apparent ease. *Grayia smythii* is aquatic, and eats fish, frogs, and tadpoles (Dunger 1971, *op. cit.*; Pitman, *op.cit.*). It might therefore use its tail for anchoring during prey capture, as in *A. anoscopus*. However, prey capture behavior in *G. smythii* is unknown (Cansdale, *op.cit.*; Dunger 1971, *op. cit.*; Pitman, *op. cit.*).

The function of the weak prehension in the tail of *Natriciteres variegatus*, a terrestrial denizen of damp places (Dunger 1971, *op. cit.*; Pitman, *op. cit.*), is enigmatic.

The tails of the terrestrial species *Boaedon lineatus* and the fossorial species *Aparallactus niger* lacked prehensile ability. This is not surprising, as stability is not a problem for a snake which tends not to occur high above the ground. However, I observed that the hind end of the trunk (immediately anterior to the tail) in both species is capable of exerting a powerful grip on a finger. The function of this hind grip in both species is enigmatic.

I thank Jim and Jane Park, John and Marie Taylor, and George and Libby Senter for allowing me to keep cages of snakes under their garage or porch roofs. I thank Alfred, Mary, and Torseh Yeanay, Earl and Ken Williams, Sam Wiah, and several individuals of unknown identity, for locating some of the snakes used in this study.

Submitted by **PHIL SENTER**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA.

LIOPHIS PORTORICENCIS ANEGADAE (NCN). **NIGHT-LIGHT NICHE**. Geckos have for years been known to associate with human dwellings, foraging around lights at night. More recently, diurnal lizard species have developed this behavior, termed "night-light niche" by Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, Florida. 720 pp.). McCoid and Hensley (1993. Herpetol. Rev. 23:87–88) listed seven species of *Anolis* and a skink (*Cryptoplepharus poecilioplеurus*), and Perry and Buden (1999. Micronesica 31:263–273) added another skink, *Lamprolepsis smaragdina*, to the list of reptiles that employ this behavior. On Guana Island, British Virgin Islands, the crested anole *Anolis cristatellus* has for years been known to occupy this niche (Lazell, unpubl.). In October 1999, the diurnal gecko *Sphaerodactylus macrolepis* was first seen in the night-light niche, with individuals seen foraging on path lights between 2030 and 2100 h (Perry, unpubl.). In the last three years, however, a diurnal colubrid snake has also joined the growing list of species foraging at lights in the night. Starting in 1997, we have observed several individuals of *Liophis portoricensis anegadae* apparently ambushing lizards at these lights. On 2 October 1999, one was observed consuming an *Anolis*, itself using the light to ambush prey. To our knowledge, this is the first record of a snake occupying the night-light niche. With this development, a chain that started with insects being attracted to lights, and then extended to insect predators, now has its first secondary predator.

We are indebted to Barry and Buena Valentine for recording the *Anolis* consumption.

Submitted by **GAD PERRY**, Department of Zoology, University of Wisconsin, 430 Lincoln Drive, Madison, Wisconsin 53706-1381, USA (e-mail: GPerry@facstaff.wisc.edu), and **JAMES LAZELL**, The Conservation Agency, 6 Swinburne St., Jamestown, Rhode Island 02835, USA.

MASTICOPHIS FLAGELLUM (Western Coachwhip). **SECONDARY INGESTION**. On 19 April 1999, at 1930 h, an adult female *Masticophis flagellum* was captured under a four-foot piece of aluminum siding at Cedar Hill State Park, Dallas Co., Texas, USA. The snake (142.0 cm total length), which appeared to have recently fed, was palped. An *Opheodrys aestivus* (rough green snake), attached to a 15.0 cm elm stem (*Ulmus crassifolia*) containing 17 leaves was regurgitated. The *O. aestivus* (ca. 50 cm total length) had wrapped its posterior half including its tail tightly around the vegetation. This suggests that the *Opheodrys* was attempting to evade predation by clinging to the elm. The *Opheodrys aestivus*, still attached to the vegetation, was preserved and placed in the University of Texas at Arlington Collection of Vertebrates (UTA-R46045). The *Masticophis* was released.

We thank Ardell Mitchell for reviewing this manuscript, and the staff of the Dallas Zoo Department of Herpetology for their support. We also thank the Texas Parks and Wildlife Department (Permit # 51-98), and the staff of Cedar Hill State Park.

Submitted by **RICHARD D. REAMS** and **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, Dallas, Texas 75203 USA, and **JOHN M. DAVIS**, Texas Parks and Wildlife, P.O. Box 941 Cedar Hill, Texas 75106 USA; e-mail (RDR): Hylareams@aol.com.

OXYRHOPUS PETOLA DIGITALIS (NCN). **PREY**. Neotropical colubrid snakes of the genus *Oxyrhopus* are known to feed on lizards and rodents (Duellman 1990. *In* Gentry (ed.), Four Neo-

tropical Rainforests, pp. 455–505. Yale Univ. Press, New Haven, Connecticut; Sazima and Abe 1991. Studies on Neotropical Fauna and Environment 26:159–164; Strussmann and Sazima 1993. Studies on Neotropical Fauna and Environment 28:157–168; Andrade and Silvano 1996. Revta Bras. Zool. 13:143–150). Birds have also been reported as prey of *O. guibei* (Sazima and Abe, *op. cit.*). Here we report the stomach contents of one *O. petola digitalis* (1287 mm total length), captured in the Municipality of Ibiporã, Paraná, Brazil. One unidentified rodent (ca. 70 mm SVL) and one bird, *Columbina talpacoti* (Aves: Columbiformes, 110 mm bill to uropygial gland length), were found in the snake's stomach. The two specimens were ingested head first. This is the first record of *O. p. digitalis* eating a bird. The snake was deposited in the herpetological collection of the Universidade Estadual de Londrina (MZUEL 150), Londrina, Brazil.

Submitted by **PAULO SÉRGIO BERNARDE** and **REGINALDO ASSÊNCIO MACHADO**, Curso de Pós-Graduação em Zoologia, Depto. de Zoologia, Universidade Federal do Paraná, CP 19020, Curitiba-PR, 81531-990, Brazil (e-mail: rmachado@garoupa.bio.ufpr.br).

SISTRURUS CATENATUS (Massasauga). **LITTER SIZE**. Female body size is known to affect litter size in snakes (Seigel and Ford 1987. *In* Seigel et al. (eds.), Snakes: Ecology and Evolutionary Biology, pp. 239–240. MacMillan Publishing Co., New York, New York). Data exist on litter size for *Sistrurus catenatus* across the species' range in North America (Fitch 1985. Univ. Kansas Mus. Nat. Hist. Misc. Pub. 76:1–76). Litter size in Illinois *S. catenatus* was 5–14 (mean = 9.5) in six litters examined (Wright 1941. Am. Midl. Nat. 25:659-672). In other states, mean litter size for this viperid ranged from 3 to 19 (Seigel 1986. Biol. Cons. 35:333–346).

On 21 July 1999 a gravid female *S. catenatus* was collected in Cook Co., Illinois, USA. The snake was retained for reproductive data as part of ongoing studies of *Sistrurus catenatus* populations in northeastern Illinois. The snake was maintained alone in an enclosure (23–28°C). The female (660 mm SVL, 520 g on 1 August 1999) gave birth to 20 neonates between 0800–1130 h on 11 August 1999. Total litter mass (taken within 1 h of parturition) was 210 g; afterbirth weight was 80 g. This yielded 290 g of total expended reproductive mass. Female post-parturition weight was 230 g. Relative reproductive effort (Lemen and Voris 1981. J. Anim. Ecol. 50:89–101), obtained by dividing total litter mass by female pre-parturition mass, was calculated to be 40.3% for this female. However, when the female's total expended reproductive mass (290 g) is divided by female pre-parturition mass, total reproductive effort was 55.7%, with 40.3% being effort invested only in neonates.

Neonates were sexed by probing, weighed on an Acculab Pocket Pro digital gram balance, and measured to the nearest 5 mm. The 20 (17 female, 3 male) neonates ranged from 200–220 mm SVL (mean ± SD = 212.3 ± 4.88 mm). Body weight ranged from 10.6–12 g. (11.51 ± 0.589 g). Neonates were individually identified by dorsal-pattern description and photographs, and were released with the female at the capture site. This litter currently represents the largest number of young known for *Sistrurus catenatus* in North America.

This study was funded by the Illinois Department of Transportation. The Illinois Department of Natural Resources, Endangered Species Protection Board (G. Kruse) provided permits to retain the gravid female *S. catenatus*. The author thanks Harold K. Voris for comments on the manuscript.

Submitted by **THOMAS G. ANTON**, Department of Zoology, Division of Amphibians and Reptiles, Field Museum of Natural History, Roosevelt Road at Lakeshore Drive, Chicago, Illinois 60605, USA (e-mail: TAnton2963@aol.com).

THAMNOPHIS SIRTALIS FITCHI (Valley Garter Snake). **DIET**. Several snakes of the genus *Thamnophis* are recognized scavengers. For example, *T. elegans*, *T. radix* and *T. proximus* are all reported as occasional carrion eaters (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). Recently, the most wide ranging garter snake, *T. sirtalis*, has been implicated as a scavenger (Sajdak and Sajdak 1999. Herpetol. Rev. 30:229). Here, we report another instance of scavenging in *T. sirtalis*.

On 9 August 1999, at Furnace Flat in the Tahoe National Forest, Nevada Co., California, USA (39°21'20.5"N, 120°30'13.6"W) we encountered a male *T. sirtalis fitchi* (SVL 486 mm, tail length 130 mm, 46.68 g, deposited in the California Academy of Sciences, CAS 209985) attempting to swallow the anterior portion of a headless fledgling fox sparrow, *Passerella illiaca* (tarsus length 160 mm, 2.46 g, held with CAS 209985). Upon our approach, the snake disengaged its jaws and fled. It was caught and palped for stomach contents but contained none. Although *T. sirtalis* are known to prey on birds (Gregory 1978. Can. J. Zool. 56:167–174), the sparrow remains were in an advanced stage of decomposition and showed no signs of being previously swallowed and regurgitated by the snake. These observations support the widely held view that *T. sirtalis* is a generalist predator eating a wide variety of prey (Fitch 1965. Univ. Kansas Publ. Mus. Nat. Hist. 15:493–564).

We thank Doug Long for help identifying the fox sparrow and Jens Vindum and Marylin Tierney for their supervision during this fieldwork. Fieldwork was funded by a Challenge Cost-Sharing Agreement between the CAS and the U.S. Department of Agriculture, Forest Service Region 5 (CCS-5-99-20-069).

Submitted by **CHRIS R. FELDMAN**, Department of Biology, San Francisco State University, San Francisco, California 94132, USA, and **JEFFERY A. WILKINSON**, Department of Herpetology, California Academy of Sciences, San Francisco, California 94118, USA (e-mail: jwilkinson@harveyecology.com).

THAMNOPHIS SUMICHRASTI (Sumichrast's Garter Snake). **PREY**. *Thamnophis sumichrasti* is a poorly known garter snake that occurs in eastern México. Data on the diet of this species is lacking. However, data on 20 species of garter snakes show that fish and amphibians are the main dietary items (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.). On 5 August 1995 we collected a young female *T. sumichrasti* (blotched morph, 117 mm SVL), at the vicinity of Carpinteros, Hidalgo, México. It was basking on the ground of a pine-oak forest. During handling the

snake regurgitated a partially digested adult *Pseudoeurycea leprosa* (Plethodontidae), that was ca. 53 mm SVL. To our knowledge this is the first record of *T. sumichrasti* preying on *P. leprosa*. The preserved snake (JLE0850) is deposited in the herpetological collection of Unidad de Biología, Tecnología y Prototipos (UBIPRO-Iztacala, UNAM).

ALSODES AUSTRALIS. ARGENTINA: CHUBUT: Departamento Tehuelches: S shore Lake Vintter, 43°58'S, 71°33'45"W, ca. 990 m elev. 2 February 2000. Carmen Úbeda. Museo de La Plata, La Plata, Argentina (MLP A 1788). Verified by Néstor G. Basso. Adult male (SVL 53.43 mm) showing secondary sex characters (distinct thorny structures in the fingers and round bilateral spiny patches on the chest). Specimen was found under a rock near a cold, crystalline mountain stream where large numbers of *A. australis* tadpoles (of varying size) were also found; recently metamorphosed juveniles were also found in adjacent streams. The environment is temperate humid deciduous austral beech forest of lenga (*Nothofagus pumilio*). *Alsodes australis* is known to inhabit austral forests of Chile and Argentina. Only three previous records exist for the species: in Chile at Puente Traihuanca (46°25'S, 72°04'W), and in Argentina at Paso Pérez Rosales (41°04'S, 71°48'W) and Arroyo Zanjón Hondo (42°42'S, 71°41'W) (Formas et al. 1997, Stud. Neotrop. Fauna & Environm. 32: 200–211). Specimen extends known distribution to the eastern slopes of the Andes 145 km air line S from the southernmost previously known locality (Arroyo Zanjón Hondo) and decreases distributional hiatus between the southernmost locality in Argentina and the only one known for Chile.

GASTROPHRYNE CAROLINENSIS (Eastern Narrowmouth Toad). USA: TENNESSEE: Williamson Co: Directly across Little Harpeth River from Deerwood Arboretum and Natural Area at end of Deerwood Lane off Johnson Chapel Road (36°01'59"N, 86°50'35"W). 21 August 1994. Robert and Andrea English. Austin Peay State University Museum of Zoology (APSU Color Slide 3320). Verified by A. Floyd Scott. Five males calling in flooded lowland behind River Oaks subdivision; water depth 1.3 cm. New county record (Redmond and Scott 1996, Austin Peay State Univ. Center Field Biol. Misc. Publ. 12:1–94).

Submitted by **ROBERT** and **ANDREA ENGLISH**, 6228 Les Waggoner Road, Franklin, Tennessee 37067, USA.

HETERIXALUS LUTEOSTRIATUS (Yellowstripe Reed Frog). MADAGASCAR: MAJUNGA PROVINCE: Antsohihy Fivondronana: Ambolobozo Firaisana, Sahamalaza Peninsula, Betsimpoaka Village (14°19'79"S, 47°57'76"E). 11 February 2000. F. Andreone and J. E. Randrianirina. Museo Regionale di Scienze Naturali di Torino (MRSN-FAZC 10479, 10482, 10508); DIEGO-SUAREZ PROVINCE: Ambanja Fivondronana: Ambanja Firaisana, Ambanja Town (13°40'72"S, 48°28'37"E). 24 February 2000. F. Andreone, J. E. Randrianirina, and M. Vences, Zoologische Staatssammlung München (ZSM 426/2000). Both verified by F. Glaw. Until now, *Heterixalus luteostriatus* has been known only from localities in the southernmost part of Madagascar (i.e., Ranohira, Kirindy, Ampijoroa-Ankarafantika, Ambalabongo, Kandany, Andranolava and Mahajanga; Glaw and Vences 1994, A Fieldguide to the Amphibians and Reptiles of Madagascar. Vences und Glaw Verlag, Cologne. 480 pp). Betsimpoaka Village is 250 air km from the northernmost published record at Mahajanga. In addition, the record from Ambanja Town is located 75 km north of Betsimpoaka Village and extends the distribution 325 km north into the region of Antsiranana. At Betsimpoaka Village, the specimens were observed overnight in the vicinity of ricefields. At Ambanja Town, the specimen collected was found calling at night in a temporary swamp, in syntopy with *Heterixalus variabilis* (much more abundant), *Hoplobatrachus tigerinus*, *Boophis tephraeomystax*, *Mantidactylus wittei*, *Laliostoma labrosum*, and *Ptychadena mascareniensis*.

FIG. 1. *Heterixalus luteostriatus*. Photographed by Franco Andreone at Betsimpoaka Village, Sahamalaza Peninsula, northwestern Madagascar.

Submitted by **ROBERT** and **ANDREA ENGLISH**, 6228 Les Waggoner Road, Franklin, Tennessee 37067, USA.

HYLODES HEYERI. BRAZIL: PARANÁ: Municipality of Morretes (25°23'S, 48°52'W). Between March 1999 and March 2000. Collector not listed. Museu de História Natural Capão da Imbuia, Curitiba (MHNCI 3575–77, 3584, 3598, 3686–87, 3766, 3770, 3774). Verified by Célio F. B. Haddad through sonogram analysis. New record for the state of Paraná; extends range ca. 100 km from the type locality, Municipality of Eldorado, state of São Paulo, Brazil (Haddad et al.1996, Copeia 1996:965–969).

Submitted by **RODRIGO LINGNAU**, Universidade Federal do Paraná, Curitiba, Paraná, Brazil and Laboratório de Herpetologia, Museu de História Natural Capão da Imbuia, Departamento de Zoológico, (SMMA/PMC), Rua Prof. Benedito Conceição, 407, CEP 82810-080, Curitiba, Paraná, Brazil.

PHASMAHYLA JANDAIA (Jandaia Leaf Frog). BRAZIL: MINAS GERAIS: Reserva Biológica de Acauã, Municipality of Turmalina (17°17'S, 42°43'W, 718 m elev.). 1 March 1989. Renato N. Feio. Museu Nacional, Rio de Janeiro (MNRJ 23629–30). Verified by José P. Pombal, Jr. Known only from Serra do Cipó in the municipalities of Conceição do Mato Dentro and Jaboticatubas, state of Minas Gerais, Brazil. Listed as "vulnerable" by virtue of habitat destruction and restricted distribution (Nascimento 1998, *In* Machado et al. [eds.], Livro Vermelho das Espécies Ameaçadas de Extinção da Fauna de Minas Gerais, pp. 456–457. Fundação Biodiversitas, Belo Horizonte, MG, Brazil). Extends range 210 km northward from known distribution, and represents the northernmost record for the species and for the genus *Phasmahyla*.

Submitted by **ULISSES CARAMASCHI**, Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Rio de Janeiro, Brazil, **CARLOS ALBERTO GONÇALVES DA CRUZ**, Departamento de Biologia Animal, Universidade Federal Rural do Rio de Janeiro, 23851-970 Seropédica, Rio de Janeiro, Brazil, and **RENATO NEVES FEIO**, Departamento de Biologia Animal, Universidade Federal de Viçosa, 36571-000 Viçosa, Minas Gerais, Brazil.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: WISCONSIN: KENOSHA CO: Town of Salem, marsh bordering Hooker Lake, N1/2, SE1/4, Sec 11, T1N, R20E. 4 May 1998. R. Hendricks III. MPM Audio Recording Catalog No. A1. Verified by G. S. Casper. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Mus., 87 pp.).

Submitted by **RUSSELL HENDRICKS III**, Lake County Forest Preserve District, 2000 North Milwaukee Avenue, Libertyville, Illinois 60048, USA.

PSEUDACRIS FERIARUM (Upland Chorus Frog). USA: TENNESSEE: WILLIAMSON CO: Flooded fields at south end of Roberts Road (35°51'17"N, 86°42'53"W). 4 December 1994. Robert and Andrea English. Austin Peay State University Museum of Zoology (APSU Color Slide 3322). Verified by A. Floyd Scott. Large breeding chorus. New county record (Redmond and Scott 1996, Austin Peay State Univ. Center Field Biol. Misc. Publ. 12: 1–94).

Submitted by **ROBERT** and **ANDREA ENGLISH**, 6228 Les Waggoner Road, Franklin, Tennessee 37067, USA.

PTERNOHYLA FODIENS (Lowland Burrowing Treefrog). USA: ARIZONA: MARICOPA CO: Vekol Valley, 11 km (airline) SW Table Top Mountain (32°41.51'N, 112°13.45'W), 600 m elev. 14 August 2000. Erik F. Enderson and Robert L. Bezy. UAZ 52026-PSV. Verified by Cecil R. Schwalbe. First record for Maricopa County; extends range 37 km (airline) NW from Santa Rosa Wash near Gu Komelik, Pinal County, Arizona (Jones and Timmons *in* Sullivan et al. 1996, Great Basin Nat. 56:38–47).

Submitted by **ERIK F. ENDERSON**, School of Renewable Resources, University of Arizona, Tucson, Arizona 85721, USA, and **ROBERT L. BEZY**, Department of Herpetology, Natural

History Museum of Los Angeles County, Los Angeles, California 90007, USA.

RANA CATESBEIANA (Bullfrog). USA: NEBRASKA: GARDEN CO: Blue Creek, 16.9 km NNE Oshkosh (41°32'N, 102°16'W). 14 June 1999. Dean A. Croshaw. Florida Museum of Natural History (UF 119756). Verified by John B. Iverson. Extends range ca. 20 km N in Garden County from the North Platte River (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **DEAN A. CROSHAW**, Department of Biology, Earlham College, Richmond, Indiana 47374, USA (e-mail: croshaw@ou.edu).

RANA CLAMITANS (Green Frog). USA: TENNESSEE: WILLIAMSON CO: Pig wallow along Seaboard Railroad tracks near Les Waggoner Road (35°52'06"N, 86°43'37"W). 22 June 1994. Robert and Andrea English. Austin Peay State University Museum of Zoology (APSU Color Slide 3323). Verified by A. Floyd Scott. New county record (Redmond and Scott 1996, Austin Peay State Univ. Center Field Biol. Misc. Publ. 12:1–94).

Submitted by **ROBERT** and **ANDREA ENGLISH**, 6228 Les Waggoner Road, Franklin, Tennessee 37067, USA.

RANA PALUSTRIS (Pickerel Frog). USA: TENNESSEE: SCOTT CO: Big South Fork National River and Recreation Area Visitor Center, Bandy Creek Campground. (36°32'27"N, 84°37'40"W). 25 March 1995. Robert and Andrea English. Austin Peay State University Museum of Zoology (APSU Color Slide 3316). Verified by A. Floyd Scott. Ten to fifteen calling males at pond. New county record (Redmond and Scott 1996, Austin Peay State Univ. Center Field Biol. Misc. Publ. 12:1–94).

Submitted by **ROBERT** and **ANDREA ENGLISH**, 6228 Les Waggoner Road, Franklin, Tennessee 37067, USA.

RANA PALUSTRIS (Pickerel Frog). USA: WISCONSIN: CRAWFORD CO: Lynxville, Sec. 23, T9N, R6W. 11 August 2000. Jordan Walley. HDW-NIU 1682–3. Verified by Harlan D. Walley. Casper (1996, Geographic Distribution of the Amphibians and Reptiles of Wisconsin. Interim Report of the Wisconsin Herpetological Atlas Project. Publ. Milwaukee Public Mus., Wisconsin. 87 pp.), cited this species from adjacent Grant and Vernon counties. Record reported herein represents the first specimens from the county.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA.

SCAPHIOPUS COUCHII (Couch's Spadefoot). MEXICO: VERACRUZ: 21.6 km NNW Cardel. 26 July 1972. R. Earl Olson. UCM 49961; 24.5 km NNW Cardel. 26 July 1972. R. Earl Olson. UCM 49962. Both verified by Richard L. Holland. First precise records for the state of Veracruz, and a range extension of ca. 300 km from southern Tamaulipas to central Veracruz (Wasserman 1970, Cat. Amer. Amph. Rept. 85).

Submitted by **HOBART SMITH**, **DAVID CHISZAR**, and **ROSANNE HUMPHREY**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: TENNESSEE: BEDFORD CO: On Pressgrove Road 0.5 km S of Kingdom Road (35°40'07"N, 86°32'38"W). 14 May 1995. Robert and Andrea English. Austin Peay State University Museum of Zoology (APSU Color Slide 3324). One specimen on road following widespread tornadoes and heavy rainfall. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1-94). On 8 August 1995 following a 7.6 cm rainfall ca. 50 calling males were recorded in a flooded field at this location. FRANKLIN CO: Old CCC Road off Highway 156 (35°15'54"N, 85°53'30"W). 7 July 1997. Robert and Andrea English. Austin Peay State University Museum of Zoology (APSU Color Slide 3314). Captured newly metamorphosed specimen in borrow pit along logging road. New county record (Redmond and Scott 1996, Austin Peay State Univ. Center Field Biol. Misc. Publ. 12:1–94). Both verified by A. Floyd Scott.

Submitted by **ROBERT** and **ANDREA ENGLISH**, 6228 Les Waggoner Road, Franklin, Tennessee 37067, USA.

THOROPA MILIARIS (Rock Frog). BRAZIL: BAHIA: Municipality of Elísio Medrado: Serra da Jibóia (12°56'S, 39°31'W). September 1995. E. M. Neto. Laboratório de Animais Peçonhentos e Herpetologia da Universidade Estadual de Feira de Santana (LAPH-UEFS 030). Verified by J. P. Pombal-Jr. and C. A. G. da Cruz. Published distribution of the species is the Atlantic Forest and derivative vegetation in the states of Espírito Santo, Minas Gerais, Rio de Janeiro, and São Paulo in southeastern Brazil; two localities are cited for Bahia, but Itaeté may well be in error, and the Itagimirim specimens were not confirmed as *T. miliaris* (Cocroft and Heyer 1988, Proc. Biol. Soc. Washington 101[1]:209–220). This Bahian record represents the northernmost for the species and for the genus *Thoropa* in Brazil.

Submitted by **RENATO NEVES FEIO**, Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, 36571-000 Viçosa, Minas Gerais, Brazil, **FLORA ACUÑA JUNCÁ**, Universidade Estadual de Feira de Santana, 44031-460 Feira de Santana, Bahia, Brazil, and **ULISSES CARAMASCHI**, Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040, Rio de Janeiro, Rio de Janeiro, Brazil.

TESTUDINES

APALONE SPINIFERA (Spiny Softshell). USA: KANSAS: BROWN CO: 1.5 mi S and 3 mi E Robinson, Sec. 14, T3S, R18E, 22 June 1994. Chris Vitt. KU Color Slide 11778. Verified by David Edds. New county record (Collins 1993, Amphibians and Reptiles in Kansas. Third Edition. Univ. Press of Kansas, Lawrence. xx + 397 pp.).

Submitted by **CHRIS VITT**, Department of Biological Sciences, Emporia State University, Emporia, Kansas 66801-5087, USA.

CHRYSEMYS PICTA (Painted Turtle). USA: KANSAS: BROWN CO: Hiawatha Country Club, Sec. 32, T2S, R17E. 5 July 1994. Chris Vitt. KU Color Slide 11777. Verified by David Edds. New county record (Collins 1993, Amphibians and Reptiles in Kansas. Third Edition. Univ. Press of Kansas, Lawrence. xx + 397 pp.).

Submitted by **CHRIS VITT**, Department of Biological Sciences, Emporia State University, Emporia, Kansas 66801-5087, USA.

GRAPTEMYS PULCHRA (Alabama Map Turtle). USA: ALABAMA: Bibb Co: Cahaba River at County Road 26 crossing. 22 April 2000. Peter V. Lindeman. Verified by Joseph T. Collins. KU Color Slide 117881. Hatchling (PL 33 mm) captured in a fyke net. New county record (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **PETER V. LINDEMAN**, Department of Biology and Health Services, 150 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA (e-mail: plindeman@edinboro.edu).

PODOCNEMIS ERYTHROCEPHALA (Redhead River Turtle). BRAZIL: PARÁ: Santarém. 1999. Collector unknown. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 639–40, LPHA 992, LPHA 1201). Verified by Marcelo E. B. Dezincourt. Pritchard and Trebbau (1984, The Turtles of Venezuela. SSAR Contrib. Herpetol. 2:1-403 + 47 color plates + 16 maps) cite old museum specimens (e.g., MCZ 3414 collected in 1886) that suggested the occurrence of the species in or near Tefé and Santarém. However, they do not affirm that the species occurs at those localities. Mittermeier and Wilson (1974): "were unable you find specimens in either of these towns in 1973, and local inhabitants were unfamiliar with the species." These specimens confirm the occurrence of the species at Santarém, at the confluence of the Amazonas and Tapajós rivers (Pritchard and Trebbau 1984, *op. cit.*; Mittermeier and Wilson 1974, Papéis Avulsos Zool. 28[8]:147–162).

Submitted by **ANA CLÁUDIA BASTOS NEVES** and **RUBENS NOBUO YUKI**, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP 68.010-200 (e-mail: acbneves@zipmail.com.br and yuki@fit.br).

PODOCNEMIS SEXTUBERCULATA (Six-tubercled River Turtle). PERU: UCAYALI: Provincia Atalaya: Bolognesi (10°02'13"S, 73°57'48"W), 175 m elev. 27 June 1998. E. Lehr. Museo de Historia Natural de San Marcos (MHNSM 20022). Verified by Uwe Fritz. First state record and southernmost record in Peru (Iverson 1994, A Revised Checklist with Distribution Maps of the Turtles of the World. Privately Published, Richmond, Indiana; Carrillo de Espinoza and Icochea 1995, Publ. Mus. Hist. Nat. UNMSM [A] 49:1–27). Specimen was obtained from a local market in Bolognesi. Dealer claimed to have caught it in the nearby Río Ucayali.

Submitted by **EDGAR LEHR**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a. M., Germany (e-mail: elehr@sng.uni-frankfurt.de).

TRACHEMYS SCRIPTA (Slider). USA: NEW MEXICO: Union Co: Clayton Lake State Park, NW shore Clayton Lake, ca. 11.7 air mi NW Clayton, UTM Zone 13 N4049484, E651324. 13 August 2000. Charles W. Painter and Bruce L. Christman. University of New Mexico Museum of Southwestern Biology (MSB 61989). Verified by William G. Degenhardt. New county record; extends range ca. 79 km NE of nearest record from Ute Creek in Harding County (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.)

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA.

AMPHISBAENIA

AMPHISBAENA FULIGINOSA VARIA. BRAZIL: PARÁ: Santarém (2°26'S, 54°42'W), village of Santa Rosa on highway Santarém–Curuá-Una (PA-370). 3 April 2000. André L. C. Canto. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1228). Verified by Rubens Nobuo Yuki. First record for state; most oriental record for the subspecies and extends the distribution at least 1600 km (Vanzolini 1951, Bull. Mus. Comp. Zool. Zool. Harvard Cambridge 106:1–65).

Submitted by **HIPÓCRATES DE MENEZES CHALKIDIS**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200 (e-mail: chalkidis@ bol.com.br).

LACERTILIA

ANISOLEPIS GRILLI. ARGENTINA: MISIONES: Departamento Iguazú, Parque Nacional Iguazú, Sendero Macuco (25°40'S, 54°30'W). 9 May 1997. J. Herrera. Colección Herpetológica de la Universidad Nacional del Nordeste, Corrientes (UNNEC 7157). Verified by Gustavo Carrizo. Adult specimen founded under rubbish of Paranaense rainforest. Third record for province; species was previously recorded in Dos de Mayo, Cainguas Department, and mouth of Rio Victoria, Guaraní Department. This record extends geographic range in Argentina 150 km northward from center of Misiones Province (Etheridge and Williams 1991, Bull. Mus. Comp. Zool. 152[5]:317–361)

Submitted by **BLANCA B. ALVAREZ,** Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400, Corrientes, Argentina.

CYCLURA CARINATA CARINATA (Turks and Caicos Rock Iguana). TURKS AND CAICOS ISLANDS: J. A. G. S. McCartney Cay. 21 January 1999. Numi C. Mitchell. Photographed only. Museum of Comparative Zoology (MCZ Color Print 10247). Verified by David Clare. Given the high specimen density we observed in regions of the island visited, and the size of the island (4.5 km x 0.25 km), J. A. G. S. McCartney Cay may support several thousand iguanas and would therefore represent an important sub-population. Extends known range ca. 16 km SE of Joe Grant's Cay and ca. 200 m N of Middle Creek Cay, Caicos Islands (Coastal Systems International, Inc. 1998. Strategic environmental assessment for Big Ambergris Cay, Turks and Caicos Islands, British West Indies. Report to the Physical Planning Department, Ministry of Natural Resources, Turks and Caicos Islands, British West Indies; Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions and Natural History. Univ. Florida Press, Gainesville. 720 pp.).

Submitted by **NUMI C. MITCHELL**, The Conservation Agency Branch Office, 67 Howland Avenue, Jamestown, Rhode Island 02835, USA, **RICK HAEFFNER**, Denver Zoological Foundation, 2300 Steele Street, Denver, Colorado 80205, USA, **MICHELLE FULFORD**, Department of Environment and Coastal Resources, Turks and Caicos Islands, British West Indies, and **WESLEY CLERVEAUX**, Department of Environment and Coastal Resources, Turks and Caicos Islands, British West Indies.

CYRTOPODION SCABRUM (Roughtail Gecko). EGYPT: Siwa Oasis (29°12'N, 25°31'E) under carpet in hotel room. 16 May 2000. Mindy Baha El Din. Field Museum of Natural History (FMNH 258501). Verified by Alan Resetar. First record from Western Desert of Egypt, 550 km west of nearest records from Cairo area (Saleh 1997, Amphibians and Reptiles of Egypt. Natl. Biodivers. Unit Publ. No. 6., Egyptian Environmental Affairs Agency, Cairo. 243 pp.). Probably recently introduced to the locality.

Submitted by **SHERIF BAHA EL DIN**, 3 Abdalla El Katib Street, Dokki, Cairo, Egypt (e-mail: baha@internetegypt.com).

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). MÉXICO: BAJA CALIFORNIA: Ensenada. 4 September–15 November 1999. Julio Arpiza-Nuñez. Herpetological collection of the Facultad de Ciencias, Universidad Autónoma de Baja California (LVFCUABC-0126). Verified by Robert L. Bezy. First record from the state of Baja California; extends the range 120 km SW from Ocotillo, Imperial County, California (Porter 1988, San Diego Herpetol. Soc. Newsl. 10:5) and 150 km SW from El Centro, Imperial County, California (Laudenslayer in Saethre et al. 1993, Herpetol. Rev. 24:155). Four specimens (18–60 mm SVL) were collected at night at a hospital in the city of Ensenada (Secretaría de Salubridad y Asistencia).

Submitted by **REYNALDO MARTÍNEZ-ISAC** and **JORGE H. VALDÉS-VILLAVICENCIO**, Facultad de Ciencias, Universidad Autónoma de Baja California, Apartado Postal 1653, Ensenada, Baja California, 22800, México.

MABUYA ALBILABRIS. AFRICA: UGANDA: Mt. Ruwenzori, Semliki National Park, Mungilo Falls. 25 August 1996. David Modry and Petr Necas. ZFMK 63296. Verified by Wolfgang Böhme. Specimen was caught in a forest clearing near a small waterfall, just at the outermost margin of the Congo basin forests at the foot of W slopes of Ruwenzori Mts. Previously only known from Guinée, Ivory Coast, Ghana, Cameroon, Guinea Ecuatorial and Gaboon (type locality) (Hoogmoed 1974, Zool. Verh. 38:3–61). Represents the first record for Uganda and is the easternmost known locality of this species.

Submitted by **PATRICK MAUSFELD** and **ANDREAS SCHMITZ**, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Herpetological Section, Adenaueralle 60, 53113 Bonn, Germany.

SERPENTES

ATRACTUS POTSCHI. BRAZIL: BAHIA: Feira de Santana (12°16'S, 38°58'W). 28 June 1993. José Silvestri. Laboratório de Animais Peçonhentos e Herpetologia da Universidade Estadual de Feira de Santana (LAPH-UEFS 454). Verified by M. T. Rodrigues. Previously known distribution was Sergipe and Alagoas, Brazil (Fernandes 1995, J. Herpetol. 29:416–419). First state record; extends distribution ca. 480 km southwest.

Submitted by **FLÁVIA MARIA PIRES LIMA**, **ILKA BIONDI DE QUEIROZ** and **FLORA ACUÑA JUNCÁ**, Departamento de Ciências Biológicas, Universidade Estadual de Feira de Santana, BA, 44031-460, Bahia, Brazil (e-mail: fjunca@uefs.br).

ATRACTUS SNETHLAGEAE. BRAZIL: PARÁ: Itaituba (4°17'S, 55°59'W) along shore Tapajós River at Fazenda Tambaú. January 1999. L. S. Rodrigues. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 855). Verified by Rubens N. Yuki. Species was known from Suriname and the states of Amapá, Rondônia, Amazônas (Manaus) and extreme eastern Pará in Brazil. First record for western Pará; fills distributional gap between the previously known localities. Specimen was collected 440 km airline from Manaus, the nearest previous record (Cunha and Nascimento 1983, Bol. Mus. Para. Emílio Goeldi Nova Sér. Zool. 122:1–42; Vanzolini 1986, Levantamento herpetológico da área do estado de Rondônia sob a influência da rodovia BR 364, Brasília, CNPq. 1-50; Cunha and Nascimento 1983, Bol. Mus. Para. Emílio Goeldi Nova Sér. Zool. 9(1):1–191; Martins and Oliveira 1993, Zoologische Mededelingen 67:21–40; Silva-Jr. 1993, Herpetol. Nat. Hist. 1:47–86).

Submitted by **JOSSEHAN GALÚCIO DA FROTA**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200 (e-mail: jgfrota@mailbr.com.br).

BOTHROPS NEUWIEDI DIPORUS (Lancehead). ARGENTINA: RIO NEGRO: Departamento General Roca: 2 km N General Enrique Godoy (39°05'S, 67°09'W). 29 April 2000. Eduardo Mendoza. Herpetological collection, Fundación Miguel Lillo, Tucumán, Argentina (FML 09439). Verified by G. Scrocchi. First record for the province of Rio Negro and southwesternmost record for the species (Cei 1986, Mon. IV Mus. Reg. Sci. Nat. Torino. 527 pp.). Nearest record for *Bothrops neuwiedi diporus* is Casa de Piedra, Department Puelen, La Pampa Province, ca. 100 km airline to the north (Tiranti and Avila 1997, Bull. Maryland Herpetol. Soc. 33[3]:97–117).

Submitted by **DANIEL ROBERTO PEREZ** and **LUCIANO JAVIER AVILA**, CRILAR-CONICET, Mendoza y Entre Ríos s/n, Caixa Postal 5301, Anillaco (La Rioja), Argentina.

CROTALUS MOLOSSUS (Blacktail Rattlesnake). USA: ARIZONA: Mohave Co: Arizona Strip District, Mule Point, N of Colorado River, N36.172886, W113.202076. 28 April 2000. Jeremiah L. La Grone and Hans F. Koenig. ASU 32960. Verified by Gordon W. Schuett. Adult male (100 cm SVL) collected at 0900 h (MST) in a rocky drainage at ca. 1630 m elev. Habitat was blackbrush plant community; an adult *Crotalus viridis lutosus* was collected <100 m from this specimen. Another adult specimen was collected from Toroweap (Tuweep) on the North Rim of the Grand Canyon National Park at N36.17967, W113.034717, 1435 m on 16 July 1995 by Ed Cummins (KU Color Slides 11779–80). Verified by Joseph T. Collins. The previous record of *Crotalus molossus* north of the Colorado River was from Trail Canyon (a tributary of

Parashant Canyon) on 19 May 1979 (LACM 136193). The spatial distance from this record to the Mule Point locality is <2 km and ca. 25 km from the Toroweap locality.

Submitted by **HANS F. KOENIG**, Arizona Game and Fish Department, P.O. Box 1269, St. George, Utah 84771, USA, and **JEREMIAH L. LA GRONE**, 2832 Bloomington Hills Drive East, St. George, Utah 84790, USA.

CROTALUS VIRIDIS CERBERUS (Arizona Black Rattlesnake). USA: NEW MEXICO: GRANT CO: 19.5 air mi W Cliff along Apache Creek at "Sid's Place," 6100 ft (1859 m) elev. NW1/4 Sec12, T16S, R21W. 7 July 2000. Bruce L. Christman and Charles W. Painter. University of New Mexico Museum of Southwestern Biology (MSB 61988). Verified by William G. Degenhardt. First verified county record (Mello 1978, Herpetol. Rev. 9:22; see discussion of this Grant County specimen in Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press. xix + 431 pp); extends range ca. 87 km south of nearest record in Catron County (Degenhardt et al., *op. cit.*).

Submitted by **BRUCE L. CHRISTMAN**, P.O. Box 180, Jemez Springs, New Mexico 87025, USA, **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, **RANDY D. JENNINGS**, Department of Natural Sciences, Western New Mexico University, Silver City, New Mexico 88062, USA, and **AARON W. LAMB**, 4 Altura Road, Santa Fe, New Mexico 87505, USA.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: NEW MEXICO: GUADALUPE CO: 48 km NW Santa Rosa, Anton Chico. 1 April 1952. R. G. Lindeborg. University of New Mexico Museum of Southwestern Biology (MSB 40970). Verified by C. W. Painter. New county record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **JAMES N. STUART**, New Mexico Department of Game and Fish, Conservation Services Division, Santa Fe, New Mexico 87504-5112, USA.

DRYMARCHON CORAIS (Western Indigo Snake). HONDURAS: ISLAS DE LA BAHIA: ISLA DE UTILA: Jerico, near Iguana Research and Breeding Station, 30 m elev. (16°6.19'N, 86°53.93'W). 4 March 2000. A. Gutsche. Forschungsinstitut und Naturmuseum Senckenberg (SMF 79719; skinned specimen without head). Verified by K. Klemmer. First record for Isla de Utila (Wilson and Meyer 1985, The Snakes of Honduras. Second Ed. Publ. Milwaukee Public Mus., Wisconsin. 150 pp.; Köhler 1998, Senckenbergiana Biol. 77:139–145).

Submitted by **GUNTHER KÖHLER** and **ALEXANDER GUTSCHE**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.M., Germany.

EPICRATES CHRYSOGASTER CHRYSOGASTER (Turks Island Boa). TURKS AND CAICOS ISLANDS: JOE GRANT'S CAY: SE end of island, ca. 150 m W Jacksonville, East Caicos. 21 January 1999. Numi C. Mitchell. Photographed and released at capture locality. Museum of Comparative Zoology (MCZ Color Print 10246). Verified by Rick Haeffner. Extends known range ca. 13 km E of Middle Caicos and ca. 30 km NNW of Long Cay, Caicos Islands (Tolson and Henderson 1993, The Natural History of West Indian Boas. R & A Publishing Ltd., Somerset, England).

Submitted by **NUMI C. MITCHELL**, The Conservation Agency Branch Office, 67 Howland Avenue, Jamestown, Rhode Island 02835, USA.

EUNECTES DESCHAUENSEEI (Dark-spotted Anaconda). BRAZIL: PARÁ: Santarém (2°26'S, 54°42'W). Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1227). 29 March 1999. Alexandre Chaves; LPHA 1233. April 1999. Collector unknown. Both verified by Rubens N. Yuki. According to Chippaux (1986, Collection Faune Tropicale XXVII. 165 pp.) and Peters and Orejas-Miranda (1970, Bull. U.S. Nat. Mus. 297:1–347), species occurs only in the Ilha do Marajó (type locality) of Pará, Brazil. This record expands the distribution 470 km west.

Submitted by **ANDRÉ LUIZ COLARES CANTO**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil. CEP: 68.010-200; e-mail: belaco@biologo.mailbr. com.br.

HETERODON NASICUS (Western Hognose Snake). USA: NEW MEXICO: MORA CO: 17.7 km N Wagon Mound, DOR. 26 August 1993. J. P Hubbard (to J. N. Stuart). University of New Mexico Museum of Southwestern Biology (MSB 56215). Verified by C. W. Painter. New county record (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **JAMES N. STUART**, New Mexico Department of Game and Fish, Conservation Services Division, Santa Fe, New Mexico 87504-5112, USA.

MICRURUS FRONTIFASCIATUS (Bolivian Coral Snake). BRAZIL: PARÁ: Almeirim (1°32'S, 52°34'W). 1999. Collector unknown. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, (LPHA 1216). Verified by Rubens N. Yuki. The specimen represents the first country record; extends known distribution ca. 1600 km airline (Peters and Orejas-Miranda 1970, Bull. U. S. Nat. Mus. 297:1–347; Roze 1983, Mem. Inst. Butantan 46:305–358).

Submitted by **ANDREI GUIMARÃES GUEDES**, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200; e-mail: andguedes@biologo.mailbr.com.br).

OXYRHOPUS MELANOGENYS MELANOGENYS. BRAZIL: PARÁ: ITAITUBA (4°17'S, 55°59'W) along shore Tapajós River. 1999. N. O. Serrano. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1319). Verified by Rubens N. Yuki. In Brazil, subspecies is known from the states of Rondônia and Amazônas (Occidental Amazonia), up to the Manaus meridian on the eastern edge of its distribution. Specimen represents first state record and extends distribution ca. 440 km (Vanzolini 1986, Levantamento herpetológico da área do estado de Rondônia sob a influência da rodovia BR 364, Brasília, CNPq, 50 pp.; Silva-Jr. 1993, Herpetol. Nat. Hist. 1:47–86).

Submitted by **JOSSEHAN GALÚCIO DA FROTA**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200 (e-mail: jgfrota@mailbr.com.br).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORIDA: Broward Co: Davie, Wolf Lake Park. 14 July 2000. K. L. Krysko, J. N. Decker, and A. T. Reppas. Florida Museum of Natural History, University of Florida (UF 120906). Verified by F. Wayne King. New county record.

Submitted by **KENNETH L. KRYSKO**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@flmnh.ufl.edu), **JOHN N. DECKER**, 5926 Thomas Street No. 18, Hollywood, Florida 33021, USA, and **ANTHONY T. REPPAS**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORIDA: Orange Co: Winter Park (28°36'N, 81°21'W), backyard at 1607 Alamo Avenue. Five individuals, all found by C. W. Brown. The first, TL ca. 10 cm, was discovered on 6 February 2000 in a pile of leaves, but escaped while being photographed. Three additional specimens, also alive and 9.1 cm, 9.2 cm and 12.6 cm respectively, were found under the same small piece of debris on 27 March 2000 and were released. The fifth specimen, with a TL of 9.1, was found dead in a pile of vegetation on 19 April 2000 and was preserved (USNM 538080). Verified by Addison H. Wynn. Northernmost and second inland record for peninsular Florida. The other inland county record is from Lake Placid, Highlands County, northwest of Lake Okeechobee (Meshaka 1994, Herpetol. Rev. 25:34). Since its discovery in Dade County (Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89; Wynn et. al. 1987, American Mus. Novit. 2808:1–7), the range of *R. braminus* has been extended by discoveries in Palm Beach County (Delorey and Mushinsky 1987, Herpetol. Rev. 18: 56), and Brevard County (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton-Mifflin, Boston, Massachusetts, 450 pp.) along the Atlantic Coast; Monroe County and the Keys in the south (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Windward Publ., Miami; Ehrig 1990, Herpetol. Rev. 21:41; Watkins-Colwell and Watkins-Colwell 1995, Herpetol. Rev. 26:210), and Lee (Conant and Collins 1991, *op. cit.*) and Pinellas (Crawford and Somma 1993, Herpetol. Rev. 24: 68) counties along the Gulf Coast. It can be expected in all Florida localities where imported plants have been introduced.

Submitted by **CARL H. ERNST**, Department of Biology, George Mason University, Fairfax, Virginia 22030-4444 (e-mail: cernst@gmu.edu), and **CHRISTOPHER W. BROWN**, Veterinary Emergency Clinic of Central Florida, 882 Jackson Avenue, Winter Park, Florida 32729, USA (e-mail: chris@itgoesboing.com).

TANTILLA RELICTA NEILLI (Central Florida Crowned Snake). USA: GEORGIA: Lowndes Co: Valdosta. 24 May 1976. J. P. Whitney. GMNH 22851. Verified by John B. Jensen. New state record (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Publ. 3:1–712). Extends range ca. 29 km NNE of previous northernmost known site (UF 118236, 1 mi S Pinetta).

Submitted by **MATTHEW J. ELLIOTT**, Georgia Gap Analysis Program, Institute of Ecology, University of Georgia, Athens, Georgia 30602, USA, and **M. ELIZABETH McGHEE**, Georgia Museum of Natural History, University of Georgia, Athens, Georgia 30602, USA.

Gelephu, Bhutan

The mountainous country of Bhutan (from the Sanskrit, meaning "highland"), which lies landlocked in the southern slopes of the Himalayas, remains biologically poorly explored. Although vast tracts of land of this relatively small country (area: 46,500 square km) are under forest cover (Das 1998; Mahat 1985), there have been few reports of its herpetofauna, the last one (Bauer and Günther 1992) being based on an old (1972) collection. Among the other published works on the country's herpetofauna are reports on crocodilians by Bustard (1979; 1980a, b) and a more general note by Biswas (1976) on a small collection from Bhutan, made incidental to an expedition in search of the Yeti (or Abominable Snowman), which supposedly haunts the higher reaches of the Himalayas.

Between 13–18 June 1999, we conducted Bhutan's first workshop on herpetological techniques for the personnel of the country's National Parks at Gelephu, southern Bhutan. During the associated field work, seven species of amphibians and twelve species of reptiles were collected.

We worked primarily in the southern region of Bhutan, in areas classified as having subtropical broad-leaved forests, at altitudes around 270 m above msl (except *Sibynophis sagittarius*, which was taken from the road between Surey and Gelephu, at an elevation of about 850 m above msl). Techniques utilized include opportunistic collecting, pitfall trapping in association with drift fences, 8 m x 8 m plot sampling, and road cruising. All specimens collected have been retained in the museum of the Royal Manas National Park (RMNP), Gelephu, Bhutan; numbers cited refer to the RMNP accession numbers ; SVL = snout–vent length. For each specimen, we provide locality and microhabitat data, date and time of capture, and measurements. Additionally, for most snakes, we provide data on pholidosis. Where relevant, species accounts have been annotated with remarks on occurrence in Bhutan, range ex-

tension, etc. Measurements were taken with Mitutoyo dial vernier calipers to the nearest 0.1 mm (for lengths up to 200 mm), or with a steel tape measure to the nearest 1 mm (for lengths >200 mm).

Most of the species being reported are characteristic of a lowland Indian fauna, although Indo-Chinese elements in the collection are also present—*Amolops marmoratus*, *Megophrys parva*, among amphibians, and *Cyrtodactylus khasiensis*, *Hemidactylus garnotii* and *Psammodynastes pulverulentus*, among reptiles. Seven species of amphibians and eight species of reptiles are added to the herpetofaunal list for Bhutan.

SPECIES LIST

AMPHIBIA

Family Megophryidae

Megophrys parva. RMNP 22. Sershong, Sarpang District. 18 June 1999. 1910 h. On trail within a secondary forest, ca. 15 m from a hill stream. Measurements: SVL 58.2 mm; tibia length 31.1 mm. Remarks: New record for Bhutan. According to Chanda (1994) and Zhao and Adler (1993), the species is distributed in India over Sikkim, (northern) West Bengal, east to Meghalaya, Bangladesh, South China, and Southeast Asia.

Family Bufonidae

Bufo melanostictus. RMNP 07. Maukhola, Sarpang District. 15 June 1999. 1130 h. Under stones, at the edge of river; RMNP 12. Maukhola, Sarpang District. 16 June 1999. 0950 h. In a pitfall trap, set at the edge of river. *Measurements:* RMNP 07. SVL 61.2 mm; tibia length 25.6 mm; RMNP 12. SVL 61.9 mm; tibia length 23.0 mm. *Remarks:* New record for Bhutan. A widespread species in South and Southeast Asia.

Family Ranidae

Amolops marmoratus. RMNP 14. Sershong, Sarpang District. 16 June 1999. 1910 h. From a boulder, in the middle of a hill stream; RMNP 15. Same data, 1915 h. *Measurements:* RMNP 14. SVL 46.5 mm; tibia length 30.4 mm; RMNP 15. SVL 37.4 mm; tibia length 23.2 mm. *Remarks:* New record for Bhutan. Dubois (1992) showed that *Amolops marmoratus* (Blyth 1854) has priority over *A. afghanus* (Günther 1858). Chanda (1994) and Zhao and Adler (1993) included Nepal, Northeast India, South China, and Southeast Asia in the distribution of the species.

Euphlyctis cyanophlyctis. RMNP 13. Sarpang, Sarpang Distict. 16 June 1999. 1105 h. Under a stone, within the town. *Measurements:* SVL 51.0 mm; tibia length 24.7 mm. *Remarks:* New record for Bhutan. Widespread in South Asia.

Hoplobatrachus tigerinus. RMNP 09. Maukhola, Sarpang District. 15 June 1999. 1510 h. Under shrubs, at the edge of a river. *Measurements:* SVL 121.4 mm; tibia length 64.7 mm. *Remarks:* New record for Bhutan. Widespread in South Asia.

Fejervarya cf. limnocharis. RMNP 08. Maukhola, Sarpang District. 15 June 1999. 1130 h. Under stones, at the edge of a river. *Measurements:* SVL 58.8 mm; tibia length 27.3 mm. *Remarks:* New record for Bhutan. Widespread in South, Southeast, and East Asia.

Rana (*Sylvirana*) sp. RMNP 10. Maukhola, Sarpang District. 15 June 1999. 1510 h. Under shrubs at the edge of a river. *Measurements:* SVL 61.2 mm; tibia length 33.9 mm. *Remarks:* New record for Bhutan. Probably a new species allied to *Rana danieli* and *R. chitwanensis*.

REPTILIA

Family Gekkonidae

Cyrtodactylus khasiensis. RMNP 06. Sershong, Sarpang District. 14 June 1999. 1535 h. Inside rotting tree trunk. *Measurements:* SVL 68.2 mm; tail length 66.5 mm. *Remarks:* New record for Bhutan. The species is known from the Darjeeling region of northern West Bengal, east to North Myanmar and the Abor region of Arunachal Pradesh, Northeast India (Smith 1935).

Hemidactylus brookii. RMNP 16. Road between Sershong and Gelephu Town, Sarpang District. 16 June 1999. 2040 h. From above a culvert, at the edge of the road. *Measurements:* SVL 48.4 mm; tail length 52.3 mm. *Remarks:* The only other known locality for the species in Bhutan is Samchi (Bauer and Günther 1992).

Hemidactylus garnotii. RMNP 02. Gelephu Town. 13 June 1999. 0800 h. From wall of a room in a house. *Measurements:* SVL 51.1 mm; tail length 60.7 mm. *Remarks:* New record for Bhutan. According to Zhao and Adler (1993) and Smith (1935), the species is distributed over Sikkim, Darjeeling (in northern West Bengal), east to Southeast Asia, and Oceania.

Family Agamidae

Calotes versicolor. RMNP 18. Gelephu Town, Sarpang Distict. 17 June 1999. 0900 h. From a rock wall. *Measurements:* SVL 95.7 mm; tail length 24.9 mm. *Remarks:* Previous records of the species from Bhutan were from Phuntsholing, Balu Jhura, and Wangdi Phodrang (Bauer and Günther 1992).

Family Scincidae

Mabuya macularia. RMNP 11. Gelephu Town. 15 June 1999. 1610 h. Under bush in a plantation. *Measurements:* SVL 65.0 mm; (regenerated) tail length 50.5 mm. *Remarks:* New record for Bhutan. The specimen matches Smith's (1935) form 4 of the species in squamation and coloration. A species complex, members of which range from India and Sri Lanka, east to Southeast Asia (Smith 1935:265–266).

Sphenomorphus indicus. RMNP 05. Sershong, Sarpang District. 14 June 1999. 1530 h. Inside rotting tree trunk. *Measurements:* SVL 69.8 mm; tail length 118.4 mm. *Remarks:* The only previous record of the species from Bhutan was from 87 km N of Phuntsholing (Bauer and Günther 1992).

Family Typhlopidae

Typhlops jerdoni. RMNP 03–04. Sershong, Sarpang District. 14 June 1999. 1430 h. Under rocks in riparian (RMNP 03) and plantation (RMNP 04) forests. *Measurements:* RMNP 04. SVL 127.2 mm; tail length 2.5 mm; RMNP 03. SVL 68.1 mm; tail length 2.4 mm. *Pholidosis:* Midbody scale rows 22. *Remarks:* Previous records of the species from Bhutan were from Samchi and Phuntsholing (Bauer and Günther 1992).

Family Colubridae

Oligodon dorsalis. RMNP 01. Sershong, Sarpang District. 13 June 1999. 1445 h. From the edge of a forest path, besides moss-covered boulder, in shade. *Measurements:* SVL 335.0 mm; tail length 54.0 mm. *Pholidosis:* Ventrals 180; subcaudals 36; midbody scale rows 15; anals 2. *Remarks:* New record for Bhutan. The species was previously reported from the Garo and Khasi Hills of Meghalaya, the Naga Hills of Nagaland (both in northeastern India), Chittagong Hill Tracts of Bangladesh, south to northern Myanmar (Smith 1943), and this is therefore an extension of range by ca. 80 km to the north bank of the River Brahmaputra.

Psammodynastes pulverulentus. RMNP 21. Sershong, Sarpang District. 18 June 1999. 1130 h. Edge of a secondary forest, ca. 15 m from a hill stream. *Measurements:* SVL 383.0 mm; tail length 80.9 mm. *Pholidosis:* Ventrals 167; subcaudals 51; midbody scale rows 17; anal 1. *Remarks:* New record for Bhutan. The species was previously reported from Nepal (Swan and Leviton 1962), east through northern Orissa (Bhowmik and Sur 1988) to northeast India, South China and Southeast Asia (Smith 1943; Zhao and Adler 1993). The Bhutanese specimen contained three neonates measuring (SVL) 128.0–136 mm. Wall (1907) had earlier reported viviparity in the species.

Sibynophis sagittarius. RMNP 19. On road between Surey and Gelephu, ca. 2 km from Surey. 17 June 1999. Mortally injured on the verge of the road. *Measurements:* SVL 459.0 mm; tail length 139.0 mm. *Pholidosis:* Ventrals 167; subcaudals 61; midbody scale rows 15; anal 1. *Remarks:* New record for Bhutan. Known to be widely distributed in South Asia (Smith 1943), including the western Himalayas, although this appears to be the first record from the eastern Himalayas.

Family Elapidae

Bungarus fasciatus. RMNP 23. Road between Sershong and Gelephu Town, Sarpang District. 18 June 1999. 2015 h. From a tarred road, entering the grassy margin. *Measurements:* SVL 1169 mm; tail tip missing. *Pholidosis:* Ventrals 221; subcaudals 8+ (tail almost entirely missing); midbody scale rows 15; anal 1. *Remarks:* New record for Bhutan. The species is widespread, from Central India, east to Southeast Asia and South China (Smith 1943; Zhao and Adler 1993), and the present record helps fill what had been a distributional gap in its known range in the eastern Himalayas.

Naja naja. Material: RMNP 17. Gelephu Town. 17 June 1999. 0900 h. Dead on road. *Measurements:* SVL 912.0 mm; tail length 189.0 mm. *Pholidosis:* Ventrals 186; subcaudals 60; midbody scale rows 23; anal 1. *Remarks:* Reported from Bhutan, without further data, by Mahendra (1984). The record may well be the easternmost for the species (see Wüster 1998; Wüster and Thorpe 1992).

Acknowledgments.—We thank the participants of the workshop on herpetology, held at Gelephu, for help with collection of many of the species mentioned. Thinley Wangchuk, proprietor of Hotel Peagadly, housed ID and permitted strange guests inside his hotel. Grateful thanks are also due to our respective institution, the Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, for permitting ID leave to conduct the workshop and for support during manuscript preparation. The Royal Manas National Park, His Majesty's Government of Bhutan, and the World Wide Fund for Nature—Bhutan Program, hosted the workshop and supported the field work. James Perran Ross helped complete a literature citation. Finally, we thank Aaron M. Bauer, Patrick David, and an anonymous reviewer for comments on this report.

The herpetofauna of the Mexican state of Puebla is poorly known (Flores and Gerez 1994); the only account for the state is that of Fugler and Webb (1956). Between 1996 and 2000 we conducted inventories of the herpetofauna of several municipalities in the state (Fig. 1). Our surveys were concentrated in the following areas and habitats: coffee plantations and cloud forest in the Sierra Norte; oak woodland, pine woodland, and cloud forest in the Sierra Negra Oriente; and arid scrub, semiarid deciduous forest, and tropical deciduous forest in the southern and central areas of Puebla.

Our surveys produced 22 new species records for the state and documented range extensions for eight others. All specimens were deposited in the herpetological collections of the Escuela de Biología de la Benemérita Universidad Autónoma de Puebla, México (EBUAP), and Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC). Identifications of all specimens were verified by Edmundo Pérez Ramos.

STATE RECORDS

ANURA

Agalychnis moreletii (Morelet's Leaf Frog). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 0.7 km SW Yohualichan, 704 m elev. (20°03'N, 97°30'W). 31 August 1998. EBUAP 1041. Found on a branch of a bush near a pond, on which three tadpoles (Stages 27, 36, 37; Gosner 1960) of this species were found. Represents a range extension of about 140 km NW of previous localities in central Veracruz (Duellman 1970).

Eleutherodactylus spatulatus (Spatulate Robber Frog). Sierra Negra Oriente de Puebla: Municipality of San Pablo Zoquitlán: 2 km E Zoquitlán, 2155 m elev. (18°19'N, 97°00'W). 15 March 1997. EBUAP 1040. This specimen, a male, was found calling from a rock crevice. Previously recorded only from the states of Veracruz and Oaxaca (Campbell et al. 1989).

Eleutherodactylus verrucipes (Bigear Chirping Frog). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: Las Hamacas, 425–530 m elev. (20°02'N, 97°27'W). 26 November 1997. EBUAP 1047–48; 0.15 km SE Santiago Yancuictlalpan, 545–565 m elev. (20°03'N, 97°28'W). 27 January 1998. EBUAP 1049–51; 1.5 km NE Santiogpan, 500 m elev. (20°04'N, 97°29'W). 28 February 1998. EBUAP 1052; Tatahuitaltipan, 3 km SW of Yohualichan, 575 m elev. (20°04'N, 97°30'W). 1 March 1998. EBUAP 1053; 1.3 km ruins of Yohualichan, 675 m elev. (20°03'N, 97°30'W). 2 March 1998. EBUAP 1054–55; Reyezogpan de Hidalgo, 605 m elev. (20°04'N, 97°29'W). 2 March 1998. EBUAP 1056; 1 km S San Miguel Tzinacapan, 840–860 m elev. (20°01'N, 97°32'W). 25 April 1998. EBUAP 1110–11; Atepolihui, 790 m elev. (20°01'N, 97°32'W). 25 April 1998. EBUAP 1109. Municipality of Zapotitlán de Méndez: 2.5 km NW Zapotitlán de Méndez, 905 m elev. 15 February 1998. EBUAP 1234. Municipality of Hutzilan de Serdán: 2 km SE Huitzilan de Serdán, 870 m elev. 30 November 1998. EBUAP 1236–37. Municipality of San Pedro Camocuautla, 1350 m elev. 21 December 1998. EBUAP 1238. Found under logs or rocks in the leaf litter on coffee plantations. Previously recorded only in the states of San Luis Potosí, Querétaro, and Hidalgo (Lynch 1970).

CAUDATA

Bolitoglossa platydactyla (Broadfoot Mushroomtongue Salamander). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 1 km SE Cuetzalan, 1020 m elev. (20°01'N, 97°31'W). 25 November 1997. EBUAP 1058; Cuahutapanaloyan: 3 km SW Santiago Yancuictlalpan, 460 m elev. (20°04'N, 97°27'W). 26 January 1998. EBUAP 1059; near Río Apulco, 275 m elev. (20°04'N, 97°26'W). 26 January 1998. EBUAP 1060; 1 km S Xocoyolo, 1350 m elev. (19°58'N, 97°32'W). 25 March 1998. EBUAP 1061; near border with Equimita, 1350 m elev. (19°57'N, 97°33'W). 25 March 1998. EBUAP 1062; El Rosario, 735 m elev. (20°00'N, 97°28'W). 26 May 1998. EBUAP 1063–65. Municipality of Zapotitlán de Méndez: 0.5 km W Zapotitlán de Méndez, near Zempoala bridge, 680 m elev. (20°00'N, 97°43'W). 15 May 1998. EBUAP 1143. Municipality of Huitzilan de Serdán: 3 km NW Huitzilan de Serdán, 935 m elev. (19°59'N, 97°42'W). 4 November 1998. EBUAP 1142. Found on a cattle ranch and coffee plantations in several microhabitats: under rocks and logs, in bromeliads, and inside leaf axils of plants. Records fill gaps in the known distribution of the species (Wake and Lynch 1976).

Lineatriton lineola (Veracruz Worm Salamander). Sierra Negra Oriente de Puebla: Municipality of San Pablo Zoquitlán: 2 km southeast of Zoquitlán, 1865 m elev. (18°19'N, 97°06'W). 17 March 1997. EBUAP 718. Found dead in a cloud forest. Although *Lineatriton* presently is monotypic, work in progress (D. B. Wake and colleagues) will alter the composition of this genus, and it is likely that our specimen represents an undescribed species (D. B. Wake, pers. comm.). Thus, its referral to *L. lineola* must be considered tentative. Previously known only from the state of Veracruz (Wake and Lynch 1976).

LACERTILIA

Diploglossus enneagrammus (Huaxteca Lesser Galliwasp). Sierra Negra Oriente de Puebla: Municipality of Eloxochitlán: El Mirador, 1500 m elev. (18°29'N, 96°57'W). 17 December 1998. Male, EBUAP 1120. Found under a rock in a pine forest. Recorded previously only from localities in central Veracruz and northern Oaxaca (Campbell and Camarillo 1994).

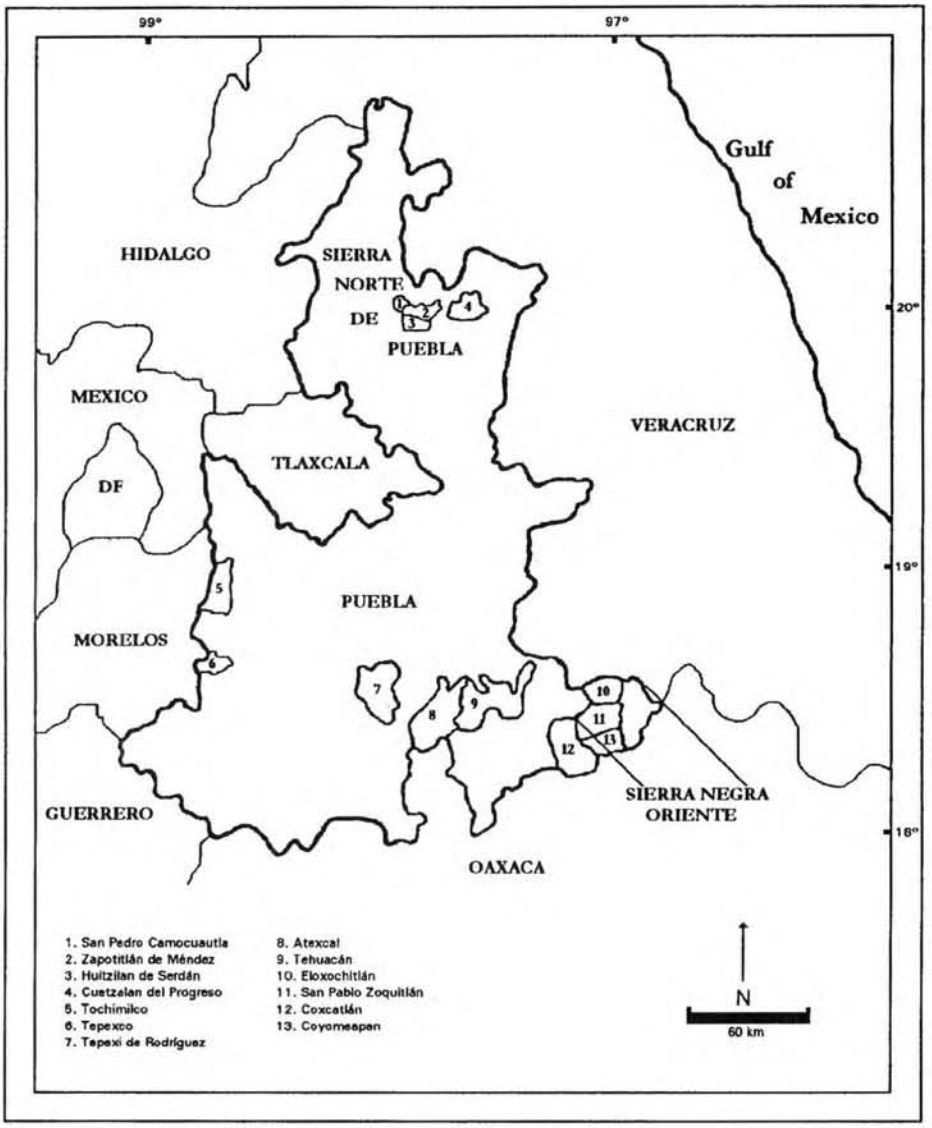

FIG. 1. A general map of the state of Puebla, México, showing the location of the municipalities mentioned in text.

Basiliscus vittatus (Brown Basilisk). Municipality of Coxcatlán: 0.05 km E of train station of Venta Salada, 1035 m elev. (18°14'N, 97°11'W). 28 June 1996. Female, EBUAP 760. Found in reeds near a water channel. Fills a gap in its previously known distribution (Lang 1989).

Corytophanes hernandezi (Hernandez's Helmeted Basilisk). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 2 km NE Zacatipan, 505 m elev. (20°02'N, 97°26'W). 14 July 1998. EBUAP 1106. Found in leaf litter on a coffee plantation. Fills a gap in its previously known distribution (Lang 1989).

Anolis laeviventris (White Anole). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 1 km SE Cuetzalan, 1065 m elev. (20°01'N, 97°32'W). 22 October 1997. EBUAP 1072; El Rosario, 875 m elev. (20°00´N, 97°32´W). 20 December 1997. Male, EBUAP 1073; Octimaxal Sur: Entrance to the cave, 1310 m elev. (20°00'N, 97°32'W). 21 December 1998. Male, EBUAP 1074; 1 km S San Miguel Tzinacapan, 840 m elev. (20°01'N, 97°32'W). 25 April 1998. Female, EBUAP 1075. Municipality of Zapotitlán de Méndez: El Puhuac: 1.5 km NW Zapotitlán de Méndez, 850 m elev. (20°47'N, 97°43'W). 9 February 1998. EBUAP 1140; 0.5 km SW Zapotitlán de Méndez, 705 m elev. 14 February 1998. EBUAP 1141. Records fill gaps between previously known localities in central Veracruz and Hidalgo (Mendoza-Quijano and Nieto-Montes de Oca 1995).

Anolis sericeus (Silky Anole). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 1 km S San Miguel Tzinacapan, 845 m elev. (20°01'N, 97°32'W). 25 April 1998. Female, EBUAP 1076; Octimaxal Norte, 805 m elev. (20°02'N, 97°30'W). 5 March 2000. EBUAP 2024. Found on a tree in a cultivated area. Records fill gaps in its previously known distribution (Lee 1980).

SERPENTES

Adelphicos quadrivirgatus (Middle American Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: Zacatipan, 600 m elev. (20°02'N, 97°26'W). 27 November 1997. EBUAP 1094; Xalpanat, 885 m elev. (20°00'N, 97°28'W). 18 December 1997. EBUAP 1112; Finca San José: 4 km ENE Santiago Yancuictlalpan, 360 m elev. (20°03'N, 97°26'W). 29 January 1998. Female, EBUAP 1095; 1 km SW Yancuictlalpan, 665 m elev. (20°03'N, 97°28'W). 30 January 1998. Female, EBUAP 1096; 1.5 km E Yohualichan, 725 m elev. (20°03'N, 97°30'W). 1 March 1998. Female, EBUAP 1097; Tatahuitaltipan: 3 km SW Yohualichan, 550 m elev. (20°04'N, 97°30'W). March 1998. Female, EBUAP 1098; Octimaxal Norte, 930 m elev. (20°02'N, 97°30'W). EBUAP 1099. Municipality of Huitzilan de Serdán: 1 km N El Paraiso, 720 m elev. 4 July 1999. EBUAP 1338. Found under logs on a coffee plantation and on a cattle ranch. The nearest records are from the foothills of the Sierra Madre Oriental, above the coastal plain, in central Veracruz (Campbell and Ford 1982).

Coniophanes fissidens (Yellowbelly Snake). Sierra Norte de Puebla: Municipality of Huitzilan de Serdán: Between Totutla and Taltzintan, 1110 m elev. (20°00'N, 97°44'W). 5 September 1998. EBUAP 1136. Found near a stream on a coffee plantation. Municipality of Cuetzalan del Progreso: 1 km SE San Andrés Tzicuilan, 1000 m elev. (20°00'N, 97°30'W). 4 May 1999. EBUAP 1146. The nearest locality records for this species are from central Veracruz (Bailey 1939).

Dryadophis melanolomus (Lizard Eater). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: Las Hamacas, 350 m elev. (20°02´N, 97°27´W). 26 November 1997. Male, EBUAP 1100;

San Miguel Tzinacapan, 805 m elev. (20°01'N, 97°32'W). 25 April 1998. EBUAP 1101; Zacatipan, 600 m elev. (20°02'N, 97°26'W). 11 July 1998. Female, EBUAP 1102; Zoquiapan: 1 km SE Cuetzalan (20°01'N, 97°30'W). 13 July 98. EBUAP 1103; Tacopixacta, 1045 m elev. (19°58'N, 97°30'W). 4 August 1998. EBUAP 1104; 2 km E Tzicuilan, 970 m elev. (20°00'N, 97°30'W). 18 September 1998. Male, EBUAP 1105. Municipality of San Pedro Camocuautla: between Tapayula and El Pasamanos, 1285 m elev. (20°01'N, 97°43'W). 15 August 1998. EBUAP 1138; 2.5 km S San Pedro Camocuautla, 940 m elev. 14 February 1998. EBUAP 1139. These specimens were found in coffee plantations, cloud or in pine-oak forests. Records fill gaps between previously known records (Stuart 1941).

Elaphe flavirufa (Tropical Rat Snake). Sierra Norte de Puebla: Municipality of Zapotitlán de Méndez: Near town of Zapotitlán, 640 m elev. (20°00'N, 97°42'W). 18 May 1998. EBUAP 1135. Nearest records for this species are from central Veracruz (Pérez-Higareda and Smith 1991).

Ficimia streckeri (Mexican Hooknose Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Preogreso: Santiago Yancuictlalpan, 600 m elev. (20°03'N, 97°28'W). 27 January 1998. EBUAP 1030; Octimaxal Norte, 880 m elev. (20°02'N, 97°30'W). 4 March 1998. Female, EBUAP 1029. Found under a rock on a coffee plantation. Southernmost record of the species, extending range about 79 km south from Castillo de Teayo, in northern Veracruz, and 138 km southeast from Zacualtipan, in northern Hidalgo (Hardy 1975).

Geophis semidoliatus (Coral Earth Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: Octimaxal Norte, 880–930 m elev. (20°02'N, 97°30'W). 4 March 1998. EBUAP 1032–35; Xalpanat, 820 m elev. (20°02'N, 97°28'W). 29 May 1998. EBUAP 1036–1037. Found in cloud forest and on coffee plantations. The nearest locality records for this species are from central Veracruz (Downs 1967).

Imantodes gemmistratus (Central American Tree Snake). Municipality of Tepexco: Calmeca, 1300 m elev. (18°38'N, 98°37'W). 3 April 1999. EBUAP 1134. The nearest locality record for this species is about 82 km at Huajintlán, Hidalgo (Zweifel 1959).

Leptophis diplotropis (Pacific Coast Snake). Municipality of Tochimilco: San Francisco Huilango, 1870 m elev. (18°50'N, 98°34'W). 20 November 1997. EBUAP 1107. Pérez-Higareda and Smith (1989) speculated that this species could occur in Puebla.

Rhadinaea hesperia (Western Graceful Brown Snake). Municipality of San Antonio Cañada: near the town of San Antonio Cañada, 1835 m elev. (18°31'N, 97°17'W). 27 May 1997. EBUAP 707. Municipality of Tepexi de Rodríguez: near the town of Tepexi de Rodríguez, 1700 m elev. (18°34'N, 97°55'W). 20 November 1997. Male, EBUAP 708. Found in arid scrub habitat. The nearest locality previously known for this species is in the state of Morelos (Myers 1974).

Rhadinaea marcellae (Marcella´s Graceful Brown Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: Xalpanat, 820 m elev. (20°00'N, 97°28'W). 29 May 1998. Male, EBUAP 1133,). Found near a waterfall in primary cloud forest. A specimen from near Tepango de Rodríguez, Puebla, was tentatively referred to *R. marcellae* by Nieto-Montes de Oca and Mendelson (1997) because it had some characteristics of *R. marcellae* and some of *R. forbesi.* Our specimen is entirely consistent with the diagnostic characters of *R. marcellae* (Myers 1974; Nieto-Montes de Oca and Mendelson 1997), thus confirming the presence of this species in Puebla.

Scaphiodontophis annulatus (Guatemalan Neckband Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 2 km SE San Andrés Tzicuilan, 1000 m elev. (20°00'N, 97°30'W). 25 April 1999. Male, EBUAP 1137; 3.5 km SE San Andrés Tzicuilan, 1000 m elev. (20°00'N, 97°30'W). 4 May 1999. Female, EBUAP 1144; 1 km SE of San Andres Tzicuilan, 985 m elev. 7 May 1999. EBUAP 1145. Found in leaf litter on coffee plantations. The nearest locality records are from central Veracruz (Pérez-Higareda and Smith 1991).

Ophryacus undulatus (Mexican Horned Pitviper). Sierra Negra Oriente de Puebla: Municipality of Coyomeapan: Coyomeapan, 2200 m elev. (18°16'N, 96°59'W). 13 May 1997. Female. EBUAP 722. Municipality of San Pablo Zoquitlán: 2 km southeast of Zoquitlán, 1825 m elev. (18°19'N, 97°06'W). 17 May 2000. EBUAP 2005–07. Found in an oak or pine-oak forest. Previously recorded only from the states of Hidalgo, Guerrero, Oaxaca, and Veracruz (Flores-Villela et al. 1992).

RANGE EXTENSIONS

Eleutherodactylus decoratus (Adorned Robber Frog). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 5 km S San Miguel Tzinacapan, near the grotto of Atepolihui, 880 m elev. (20°00'N, 97°32'W). 28 April 1998. EBUAP 1042–44. These males were calling in the rain at night in a cloud forest near Río Atepolihui. Previously known in Puebla from Tepango de Rodríguez, about 20 km to the East (Camarillo and Aguilar 1995).

Diploglossus legnotus. Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 0.1 km SW Xocoyolo, at entrance to a cave, 1450 m elev. (19°58'N, 97°32'W). 20 March 1998. EBUAP 1067; 2 km NE Xocoyolo, near Vista Hermosa, 1345 m elev. 22 March 1998. Male, EBUAP 1068; 3.5 km W Xocoyolo, 1210–1225 m elev. (19°59'N, 97°33'W). 24 March 1998. EBUAP 1069–70. Found inside fallen trunks of tree ferns or under logs and rocks on a cattle ranch surrounded by cloud forest. This recently described species was previously recorded only from its type locality of Tepango de Rodríguez (Campbell and Camarillo 1994). The current records extend the known range 27 km southeast of type locality.

Anolis naufragus (Hidalgo Anole). Sierra Negra Oriente de Puebla: Municipality of San Pablo Zoquitlan: Sección segunda de Zoquitlán, 2150 m elev. (18°19'N, 97°00'W). 23 June 1996. EBUAP 710; 2 km E Zoquitlán, 2155 m elev. (18°19´N, 97°00´W). 15 March 1997. MZFC 10478; 2 km SE Zoquitlán, 1870–2135 m elev. (18°17'N, 97°04'W). 16 March 1997. EBUAP 711–14, MZFC 10477. Found in rock crevices or on branches of bushes in cloud forest. Represent a range extension about 190 km southeast of the previous record for the state at Tepango de Rodríguez (Nieto-Montes de Oca 1994).

Scincella gemmingeri (Forest Ground Skink). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 5 km SE

Xocoyolo, near of Río Apulco, 920 m elev. (19°57'N, 97°32'W). 23 March 1998. EBUAP 1077; 3.5 km W Xocoyolo, 1225 m elev. (19°59'N, 97°33'W). 24 March 1998. Female, EBUAP 1078; El Rosario, 735 m elev. (20°00'N, 97°28'W). 26 May 1998. Female, EBUAP 1079; Xalpanat: Road to San Carlos, 870 m elev. (20°00'N, 97°28'W). 27 May 1998. Female, EBUAP 1080; border between Xalpanat and El Rosario, 805 m elev. (20°00'N, 97°28'W). 29 May 1998. Male, EBUAP 1081. Found in leaf litter and under logs. Previously known in Puebla only from Tepango de Rodríguez (Camarillo 1995), about 25 km west of our localities.

Lepidophyma sylvaticum (Madrean Tropical Night Lizard). Sierra Norte de Puebla: Municipality of Cuetzalan del Progeso: Las Hamacas, 325–420 m elev. (20°02'N, 97°27'W). 26 November 1997. Females, EBUAP 1082–84; Barranca Tzitzicapan, 0.1 km SE of Santiago Yancuictlalpan, 565 m elev. (20°03'N, 97°28'W). 27 January 1998. Female, EBUAP 1085; Between Tacoapan and Coapan, 400 m elev. (20°04'N, 97°28'W). 28 January 1998. Female, EBUAP 1086; Texochico: 2 km ENE Santiago Yancuictlalpan, 495 m elev. (20°03'N, 97°27'W). 29 January 1998. Female, EBUAP 1087; 0.2 km NE Santiogpan, 600 m elev. (20°04'N, 97°29'W). 28 February 1998. Female, EBUAP 1088; Tzonchomala, 540 m elev. (20°04'N, 97°30'W). 2 March 1998. Male, EBUAP 1089; 0.5 km SW San Miguel Tzinacapan, 850 m elev. (20°01'N, 97°32'W). 25 April 1998. Female, EBUAP 1090; 5 km SW San Miguel Tzinacapan, Montaña Alaxapota, 1100 m elev. (20°00'N, 97°33'W). 27 April 1998. Female, EBUAP 1091; Ayoapan, 860 m elev. (20°02'N, 97°31'W). 29 April 1998. Male, EBUAP 1092; Xalpanat, 670 m elev. (20°01'N, 97°28'W). 28 May 1998. Female, EBUAP 1114; border between El Rosario and Tenango, Río Cuitchat, 695 m elev. (20°01'N, 97°29'W). 29 May 1998. Female, EBUAP 1113; Zacatipan, 600 m elev. (20°02'N, 97°26'W). 10 July 1998. EBUAP 1093. Found under logs and in rock crevices on coffee plantations and in cloud forest. Previously known in Puebla only from Tepango de Rodríguez (Camarillo 1995), about 25 km west of our localities.

Xenosaurus rectocollaris (Pallid Knob-Scaled Lizard). Municipality of Tehuacán: 1 km NE Santa Ana Teloxtoc, 2170–2205 m elev. (18°23'N, 97°34'W). 1 October 1996. EBUAP 734–35. Municipality of San Martín Atexcal: Cerro Gordo in San Lucas Teteletitlán, 2502 m elev. (18°21'N, 97°38'W). 24 October 1996. EBUAP 736–37. Found in rock crevices in semiarid habitat. Previously known in Puebla only from a record near Chapulco (Smith and Iverson 1993), about 59 km northeast of our localities.

Coniophanes imperialis (Black-Striped Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: 1.5 km E Yohualichan, 725 m elev. (20°03'N, 97°30'W). 1 March 1998. EBUAP 1038; Zacatipan, 600 m elev. (20°02'N, 97°26'W). 11 July 1998. EBUAP 1039. The first specimen was found under a rock on a coffee plantation, the second was in the town proper. Previously known in Puebla only from Tuzamapan de Galeana (Mejenes-López et al. 1999), about 9 km northwest of our localities.

Tantilla morgani (Morgan's Black-headed Snake). Sierra Norte de Puebla: Municipality of Cuetzalan del Progreso: Octimaxal Norte, 930 m elev. (20°02'N, 97°30'W). 4 March 1998. EBUAP 1031. Known previously only from the holotype (Hartweg 1944) from Necaxa, about 57 km northwest of Octimaxal Norte. Second specimen of this rare endemic species from Puebla. In the original description, the snout–vent length was not mentioned. The specimen reported herein has a snout–vent length of 440 mm, tail length of 30 mm (tail incomplete), and 151 ventrals (vs. 149 for the holotype).

Acknowledgments.—We thank I. Fentanes, A. Castillo, L. E. Chong, L. López, L. Oliver, E. Peña, and S. Larios for their help with the field work. Comments on the manuscript were provied by J. R. Mendelson III, W. L. Hodges, O. Flores-Villela, and A. Nieto-Montes de Oca. This research was supported by Comisión Nacional para el Conocimiento y Uso de la Biodiversidad (CONABIO), grant no. FB281/H330/96 and FB444/L283/97.

Vacancy in Herpetology

The National Museum of Natural History, Leiden, The Netherlands has a vacancy for the position of

Deputy Curator of Reptiles and Amphibians

(male/female)
(32 hours per week)

Because the present Head of the Department of Vertebrates and Curator of Amphibians and Reptiles has become involved in international nature conservation matters, a task consuming a large part of his time, and necessitating considerable travel abroad, as of January 1, 2001 a temporary position has been opened for two years for a herpetologist to look after most aspects of the work of the Curator of Reptiles and Amphibians.

Depending on acquired skills and published results a salary of Dfl. 65.000 – 90.000 per year (including vacation allowance and incorporation into the Pensionfund) can be offered.

For further information about the function (requirements and tasks) see the internet page of the museum (www.naturalis.nl) for a full advertisement text (click on "Algemeen" and "Vacatures") or contact Dr. M.S. Hoogmoed, tel. +31 71 5687618, e-mail: hoogmoed@nnm.nl.

BOOK REVIEWS

Herpetological Review, 2000, 31(4), 263–266.

The status of amphibian research has been greatly enhanced as a result of a series of landmark publications. The Vial-edited volume *Evolutionary Biology of the Anurans* (1973), Frost's *Amphibian Species of the World* (1985), Duellman and Trueb's comprehensive textbook, *Biology of Amphibians*, the ongoing series *Amphibian Biology* edited by Hal Heatwole (providing a parallel with the respected *Biology of the Reptilia*), and more recently (1999), McDiarmid and Altig's *Tadpoles–The Biology of Anuran Larvae*, have all helped to raise the profile of amphibians as a major interest group. At long last, amphibian biology seems to have come of age and is gradually taking its place alongside bird and mammal research. This change originated in the US, and has motivated the efforts of researchers around the world. There can be no doubt that *Patterns of Distribution of Amphibians* is destined to become the standard reference on amphibian zoogeography. It is an impressive book containing a breathtaking wealth of detail, while at the same time encompassing an extraordinarily broad subject area. Bill Duellman has assembled, managed and, it appears, cajoled a team of eight eminent amphibian workers from across the world to produce a remarkable reference volume. Much of the material included in the book was originally prepared for a symposium on amphibian distributions held at the Second World Congress in Adelaide in December 1993. That the volume was completed with no little pain to both its editor and the contributors is evident from a typically dry Bill Duellman comment in the Preface: "This project has evolved since the World Congress, as have the amphibians of the world and, indeed, even the position of the major tectonic plates"(!). The production of specialist scientific works like *Patterns* represent a considerable act of faith and goodwill on the part of editors, contributors, and publishers around the world; long may such efforts continue.

The inclusion of such an enormous mass of detailed information makes the book a daunting proposition for both reviewer and newcomer alike. Tables, charts, complex diagrams, and maps abound, together with comprehensive lists and appendices summarizing the geographical and altitudinal ranges of not merely hundreds but thousands of species across the world. The advice to the reader, particularly a final-year undergraduate or new postgraduate reader is, 'Take a deep breath—and plunge in.' For the specialist, biased in respect of a particular geographical area, there is much to be gained from a well-written account of his/her chosen region and still more from reading about other areas. For the novice, the detail may be more than is wanted or needed; selective

reading and culling of information from abstracts, maps, and headings to identify the most relevant sections are the order of the day. The book is arranged into ten chapters following a logical, geographical sequence.

Chapter 1 is the key chapter in the book. It provides an insight into some of the major difficulties encountered when synthesizing information into a book-length treatment. *Contra* Duellman's Preface remark, it is hardly surprising that "no modern synthesis of amphibian distributions exists." The scope of the subject is immense and the available information, detailed for some species, is almost non-existent for many/most others. Worse is the lack of a robust phylogenetic framework for a vertebrate group whose importance as an indicator of the state of the environment is becoming increasingly acknowledged. Progress in zoogeography is severely hampered by deficiencies in our knowledge of phylogeny at low, medium, and high levels.

In Chapter 1, Duellman sensibly used input from the other eight authors as well as Frost (1985) and his own (1993) additions and corrections to Frost's *Amphibian Species of the World*, to derive statistics relating to geographical distributions. The lack of a sound systematic arrangement of the Anura is immediately evident (see p. 2). It is ironic that the most stable scheme—that for the caecilians—is the one that has received least attention. Duellman comments that the classification he follows does "not necessarily reflect the phylogenetic relationships of many family-groups of amphibians," and that this is "especially evident" in the case of neobatrachian families, citing Ford and Cannatella (1993) as his reference. Duellman's Table 1:1 does not follow Frost (1985) or Duellman (1993) in at least one respect; in those references *Ascaphus* was placed in the Leiopelmatidae. Can Ascaphidae have come from Ford and Cannatella (1993)? No, it does not appear (as such) in that paper where the authors solemnly inform their readers that *Ascaphus truei* is one of the two anuran clades, *Ascaphus* being monotypic, the name *Ascaphus* being redundant with the taxon *truei* (!). Duellman's Table 1:1 also retains the Discoglossidae in the sense of including three Palaearctic genera—namely *Alytes*, *Bombina*, and *Discoglossus*; Ford/Cannatella split Bombinatoridae off from the Discoglossidae, separating *Bombina* from *Alytes* and *Discoglossus*. Can the listing of families have derived from Duellman (1975)? No, because it includes the Mantellidae, not recognized in that paper. Small wonder then, that "present familial classification does not reflect the phylogenetic relationships of many family-groups of amphibians;" one is tempted to ask "Which familial classification?" How easily new classifications/rearrangements of amphibian families arise with no justification for changes given! In a different vein, the criticism of celebrities and politicians who support the conservation of so-called 'fashionable' groups like birds and mammals is regrettable. It should be possible to argue for amphibian conservation without deriding the claims of other groups and their supporters. The section on "Threats to Amphibian Diversity" is excellent—at first; a pattern which is also followed in the sections on 'Declining Amphibian Populations' and 'Future Challenges.' The argument that scientific collecting accounts for "less than 1% of the annual regulated take of amphibians and reptiles" ('Harvesting and Collecting' p. 18) leaves itself open to the criticism that without it there would be a 1% reduction in the pressure on natural populations. If the conservationist is sincere in his/her aim to conserve, he/she should do all they can to pose no additional threat. How many field workers have *really* tried to explore alternatives to collecting? The conservationist lobby might reasonably pose the question: "Which has primacy—amphibian conservation or the right of the individual to do research on amphibians?" The comment "Because of the burgeoning amount of international, national, and state regulations, biologists and conservationists are frustrated in their efforts to obtain the kinds of documentation necessary for their research." ('Declining Amphibian Populations' p. 19) sounds like special pleading. Comments in the same vein are to be found under 'Future Challenges' ('Legislation') where the author recommends that scientific collection be separated from commercial regulation "with the implementation of scientific procedures placed in the hands of scientists." Surely even "informed biologists" do not actually *make* laws (p. 25), nor can they be presumed to be any less disinterested in the outcome of legislation which may affect their professional activities than those who are "unduly influenced by commercial considerations." If research funding is to be provided by outside agencies ("private foundations," "national and multinational corporations"), the actions of the researchers they fund will reflect upon the image of the companies concerned, and companies will legitimately demand to be consulted on research procedures and ethics.

Chaper 2—Duellman and Sweet on amphibians of Nearctic North America—was especially well written. The maps and the information in this chapter will be welcomed by undergraduate and graduate students. Information comes thick and fast making this, like most of the other chapters in the book, a valuable reference work. The section on 'Natural Regions of North America' was very useful but I found the use of specialist terminology a little intrusive—what is a 'craton,' an 'exotic terrane,' when were the Ordovician, the Taconian, Acadian, and Appalachian episodes, where was the Iapetus Ocean, and what is 'an orogenic episode'? All these terms appeared in less than 10 lines of text; a glossary would have been welcome. The volume of fascinating information on the plethodontid salamanders made me realize—yet again—what a superb group they are for an aspiring researcher. Just the 'right' number of species, occupying a well defined geographical region with a wonderful balance between what is known and what is open to future discovery, accompanied by a good supporting literature. Graduate students seeking a research topic, take note. The section on Historical Biogeography was particularly interesting, likewise that on Phylogeny and Patterns of Distribution. The statement that the only Mesozoic anuran definitely assigned to a family is *Paradiscoglossus americanus* ignores the claim of *Scotiophryne* from Montana and Wyoming described by Estes (1969), which provides additional evidence for the presence of the *predominantly* (though not exclusively) European family Discoglossidae in North America. I suspect there are others.

Jonathan Campbell's contribution on Middle American amphibians (Chapter 3) was a particularly enjoyable read; his interest and expertise in the subject is evident. Jargon still presents an occasional problem for the uninitiated: "...elevation and resulting adiabatic lapse rates..." and "...the complexity of edaphic conditions..." No explanation is offered for these terms but I did learn that terranes are "regions of distinctive geology, bounded by faults." Maps and tables are plentiful but not overdone. Campbell's chapter is characteristically well written and well thought out; gradu-

ate students intending to carry out fieldwork in Middle America will greatly appreciate his note on areas most in need of study (p. 114). In fact, for the newcomer to research on the amphibians of this region, the text is full of useful items of information, from data on rainy seasons, dry periods, and vegetation zones.

Hedges had the benefit of writing on a fascinating zoogeographical region—the West Indies (Chapter 4). His is a well-balanced contribution, which is unfortunately marred by poor quality diagrams and proof reading. The inclusion of dendrograms of the biogeographic regions based on estimates of amphibian faunal similarity was a good idea. Unfortunately, all but one of these dendrograms are out of synch with their text—a fault that could, and should, have been corrected at proof stage. The dendrogram for Cuba appears within the text for Jamaica, that for Jamaica under Hispaniola. The one for Hispaniola is in its proper place, while those for the Puerto Rican Bank and the Lesser Antilles are to be found under the Lesser Antilles and Bahamas Bank respectively, while the Bahamas Bank having only two species, *Osteopilus septentrionalis* and *Eleutherodactylus planirostris*, does not qualify for a dendrogram of its own. The quality of the maps was variable throughout the book, but they were poor in this chapter and, personally, I found the unaligned maps of Jamaica and Hispaniola particularly irritating. The amphibian density maps for Cuba (Fig.4:8) and Hispaniola were the worst, spoiled by converging contour lines. Fig. 4:17 conveys little and the arrows indicating the total area of each island are missing. I would also like to know how, in respect of *Eleutherodactylus pezopetrus*, a single locality "encompasses a range in elevation." One oddity I did pick up; Hedges referred to an important and "relatively small radiation of bufonids" as the *Bufo peltocephalus* group. In doing so, he either ignores the existence of the genus *Peltophryne* Fitzinger, 1843, which is endemic to the Greater Antilles, or else fails to provide comment or reasons for preferring their inclusion in an already unwieldy and speciose *Bufo*. No mention of *Peltophryne* is made in the paragraph on endemism in the West Indian amphibian fauna spanning pages 227–228.

Duellman obviously did the lion's share of the work on this volume, not only acting as Editor but also writing two chapters as sole author and co-authoring a third (reviewed above) with Samuel Sweet. One of these chapters (Chapter 5) covers South America—a region with the highest species density (more than 1700 species)—the Neotropics. Duellman's comments about the amphibian fauna being the richest in the world—1742 species in 140 genera and 16 families—echo Darwin's comments about stepping out into a tropical forest for the first time. For once, presenting the information in hard figures provided a fascinating perspective on the origins and diversity of the South American fauna. 94.4% of the amphibians in South America are anurans, and the remaining 5.6% are still significant in that approximately one-half of the world's caecilian species are to be found here. The region supports 64.8% of the world's species of *Hyla*, only 22% of *Bufo* and a minute 1.3% of all *Rana* spp. (only three species). This chapter was a massive undertaking and Bill Duellman fully accomplished his task. To complain about the quality of the maps sounds paltry but I hope that it might be possible to improve their quality in subsequent editions.

Borkin (Chapter 6) may have had only some 10% of the species that Duellman had to contend with, but the land surface area, topology, and climatic range of his region—North Africa, Europe, Western Asia, and the old Soviet Union—coupled with a literature in a diversity of languages made his task far from 90% easier! As Duellman says in the Preface, Borkin has provided a great service to western herpetologists in opening up the eastern European and Russian literature. Eurasia spans from the Atlantic to the Pacific an area with an enormous diversity in landscape and climatic conditions (from below sea level to the Himalayan chain of mountains, from arctic temperatures to hot deserts). There has been a significant growth in systematic studies and, not mentioned by Borkin, a growth in phylogenetic interpretation of taxa. This trend has the possibly unfortunate effect of proliferating species. But perhaps the most significant barrier to progress has been the "lack of a tradition in herpetology to analyze the distribution of amphibians throughout the Palearctic as a whole." This understates a situation which Borkin attempts to, and succeeds in, putting right. Borkin's case for regarding the Arabian Peninsula as part of the Afrotropical Realm is unconvincing; it is not proven or even well substantiated. His argument hinges chiefly on an interpretation of relationships of members of the genus *Bufo*, which I personally regard as incorrect. The evidence, such as it is, suggests the Arabian Peninsula is part of the Palearctic as is Iran, areas best considered as transition zones with a primarily Palearctic fauna—a status even more appropriate in the case of Afghanistan, Pakistan, and northwestern Nepal. Not so northwestern India, the amphibian fauna of which is best described in Borkin's own words: "Some Palearctic species have infiltrated into northwestern India." Dubois' description of the Himalayas as part of the Tibetan zoogeographical region is appropriate, since it comprises (as Borkin neatly says) "two secondary centres of independent faunal differentiation." I liked the section on the southeastern boundary of the Palearctic; a real problem zone but an area of intense biogeographical interest. The maps in this chapter are excellent, the best in the book; perhaps Duellman should have put Borkin as OC in charge of maps!

The chapter by Zhao on the amphibians of temperate eastern Asia is one of the shortest in the book, just 22 pages (Chapter 7), the same length as Tyler's on the Australo-Papuan area (Chapter 10). In both cases this is a surprise given the number of species in each of the two areas. Like Borkin, Zhao has been instrumental in opening up a fauna of an area and its associated literature to western audiences. The area of this region he had to deal with is half as large again as Australo-Papua, and two-thirds the size of South America, yet it is the least well explored. Zhao comments with a refreshing honesty that he has little or no personal knowledge of the landscapes and environments in much of this part of the world (hardly surprising in an area approaching 12 million square kilometers), and that the survey he presents must be regarded as preliminary, providing only a rough picture of amphibian distribution patterns in the region. As Zhao comments, some species are conspecific with others, others are cryptic species within a complex and there are many new taxa awaiting description. Zhao's contribution must have been one of the most difficult to write because of the paucity of information. I expect it will provide a fresh impetus for renewed interest in this important yet enigmatic region.

Inger provides a useful treatment of the distribution of southern Asian amphibians (Chapter 8). His comments echo the problems arising from the lack of stable phylogeny at almost any taxonomic

level, which provides an impediment to further progress on interpreting amphibian distribution patterns. Inger follows Ford and Cannatella (1993) without really explaining why (except for noting that little else is available). There is an element of opinion unsupported by evidence in this chapter—Ford and Cannatella (1993) is adopted; Frost (1985) is followed; Dubois' (1992) arrangement of the Ranidae is disliked but partially followed nonetheless—an action which he explains "does not signify thoughtful agreement with Dubois's (sic) decisions." This comment is followed immediately with "On the other hand, parts of Dubois's classification probably will be supported by future phylogenetic studies." These comments, and the attitudes expressed by Duellman in his introductory chapter, Frost (1985), Ford and Cannatella (1993), and Dubois (1992) in their papers, go some way towards providing an explanation for the currently perceived state of taxonomic chaos. There is a tendancy for authors to bemoan the literature on anuran taxonomy and to express a critical opinion based on gut-feeling. This practice pervades the literature either on, or citing the results of, anuran systematics. Inger provides examples of this practice in action. "I also use *Limnonectes* as defined in Dubois (1987), except for those moved to *Hoplobatrachus* by Dubois (1992), although the phylogenetic basis for this taxon is dubious; *further study almost certainly will establish the paraphyly of this group*." (my italics). Nonetheless, Inger's chapter provides a useful review of the current literature on southern Asia.

John Poynton's chapter on amphibian distributions in sub-Saharan Africa, Madagascar, and the Seychelles provides an excellent synthesis of the available data on a difficult region (Chapter 9). If the comment: "The preliminary nature of this treatment needs to be emphasized at the outset" was justified at the beginning of the chapter, it is scarcely so by the end. I understand the sentiment that much about the amphibian fauna remains unknown to us, but I do not believe that it follows that we are in the state of ignorance about the African fauna that Poynton seems to suggest. Africa is a continent of contrasts; climate and topology interact to create many different regions and ecological niches. While the land surface area to the north of the equator exceeds that of the south, there is a greater area above 1000 meters in the south. Add to this extensive climatic and vegetation changes (even over historical time) and the scenario is one of extremely complex faunal zonation. Links with South America to the west—Madagascar and India to the east and (less frequently mentioned), with Antarctica and Australia to the south and southeast, when Africa formed a central part of the southern supercontinent Gondwanaland—demonstrate the significance of Africa in any understanding of global distributions of both fauna and flora. I enjoyed Poynton's description of the biogeographical regions and provinces, and his advocacy of an Afrotemperate fauna—the latter is a significant contribution to the understanding of African amphibian zoogeography.

Tyler's chapter on the distributions of Australo-Papuan frogs was disappointing. It is hard to believe that the amphibian fauna of the "entire region" really is as poorly known as is claimed. Revised estimates of species numbers and a rapid increase in species descriptions are a global phenomenon—in some parts of the world at a faster rate than in Australia. It would have been interesting to have had an objective basis for the comments that "Perhaps only 50% of the fauna has been described" (Abstract) and "I suspect that the total fauna of New Guinea includes about 400 species, about twice the number known today." A diagram to show discovery rates of amphibians against time as included by other authors e.g., Duellman and Sweet (N. America), Hedges (West Indies), Duellman (South America), Borkin (Eurasia and N. Africa)—the last two surely more arduous to produce than the equivalent for Australia—would have gone some way towards providing some justification for these claims. The 'Material and Methods' section is really 'Description of the Regions,' with the last paragraph referring to sources of data for the species lists in separate appendices for Australia and New Guinea and Australo-Papuan archipelagos and islands. The best sections are the 'Physical Components' section and the very brief 'Patterns of Amphibian Distribution' but even these read more like an expanded abstract than sections in a major contribution. Tyler mentions having to write this chapter while suffering a prolonged period of ill health; the assistance of a co-author would have been invaluable.

This is an excellent book, and it was a genuine pleasure to review. It will be an important addition to libraries in natural history museums and university biology departments. Unquestionably one of the most important books on amphibians to appear in the last decade or so, it should be drawn to the attention of, and read by biogeographers working on other groups. Amphibian systematists and zoogeographers will undoubtedly want to have their own copy.

In a herpetological world which is now dominated by the English language and with systematics codified by an International Code of Zoological Nomenclature, it is difficult to imagine herpetology at the beginning of the nineteenth century. Less than a half-century since Linnaeus published the final edition of his Systema Naturae, the vast majority of taxonomic publications since then had been in Latin, German, French, or Dutch. Many of the new names were based on earlier scanty, often fanciful descriptions by travellers unfamiliar with biology and willing to uncritically accept and publish the tales of fellow travellers. Access to the literature was difficult, with researchers mostly working in isolation and with limited resources, and in most cases, without any field experience with their subjects.

Working with all these constraints, George Shaw, Keeper of Natural History at the British Museum, produced four works in English that have had a major impact on herpetology, although none was conceived as predominantly herpetological in nature. In 1790, he named five lizards and one frog and provided descriptions and illustrations of several additional snakes and lizards in the natural history Appendix to John White's "Journal of a Voyage to new South Wales" (reprinted 1962 by Angus and Robertson, Sydney, with a facsimile reprint published 1971 by Arno Press, New York; see also Nelson 1998, and Bauer 1999). In 1794, he produced a more specifically zoological publication, "The Zoology of New Holland" (facsimile reprint 1998 by the Friends of the State Library of South Australia, Adelaide), which named another two new Australian reptiles, including the first turtle. These two publications introduced the herpetofauna of Australia to the rest of the world.

In 1789, in collaboration with Frederick Nodder (later replaced by Elizabeth and then Richard Nodder), he began a multivolume series, "The Naturalist's Miscellany," which was to continue publication until his death in 1813, after which it was continued until 1817 by his successor, William Leach, under the title "The Zoological Miscellany." Herpetological accounts covering a variety of species appeared in these volumes.

Finally, in 1800, he began the series "General Zoology," which appeared in 14 volumes, bound as 28 parts. As with "The Naturalist's Miscellany," the series was incomplete on his death, and was later completed by J. F. Stevens, with the last volume appearing in 1826. Volume Three, covering "Amphibia" in two separately bound parts (Testudines, Ranae, Lacertae in one, Serpentes in the other), appeared in 1802. Shaw, like Linnaeus, included reptiles in the Class Amphibia, although recognizing an Order Reptilia within it to include chelonians, anurans, urodeles, crocodilians, and lizards, the latter three under the classification Lacertae. Serpentes, on the other hand, included anything limbless or almost so, and so covered amphisbaenians, caecilians, and several serpentiform lizards and urodeles.

These two volumes were not only the first post-Linnean herpetological publication of world-wide scope in English, but were also specifically written for a popular audience. They drew together the earlier accounts of a diverse range of authors and combined them with Shaw's own observations on collections in England, providing a starting point for herpetology in England and at the British Museum and leading directly to the nineteenth century dominance of Gray, Günther, and Boulenger in herpetology. As a popular work, they are profusely illustrated, with 140 black and white plates plus a frontispiece for each part. Although Shaw stated that these were "engraved principally by Mr. Heath," who signed 86 plates, 16 other artists are also indicated (Hill the next most frequent [37 plates], the others being Arnoldi, Barnfield, Bateman, Beale, Blakemore, Brown, Coates, Dixon, Grant, Harwood, Reading, Russell, Stalker, Strafford, and Wilson, none of whom contributed more than two plates). Additionally, many of the illustrations presented are copied from earlier works, only some of which are indicated (as a contribution to tracing the source of these illustrations, I note that the plates of Australian reptiles, plates 16, 65, 81, 110 and frontispiece to Part II, are redrawn from illustrations first appearing in White's "Journal of a Voyage to new South Wales," and Shaw's "Zoology of New Holland," with the illustrations of the Muricated Lizard (plate 65) and the two snakes (frontispiece and Plate 110) being reproduced in reverse, and with an extra terminal coil added to the Crimson-sided Snake). The quality of the illustrations therefore varies markedly, from accurate and beautiful representations to the bizarre (e.g., the two illustrations of the Horned Toad on plates 48 and 49, while many of the snake plates are sufficiently horrific to turn a sensitive child off herpetology for life!). As a popular work, it is also not exclusively taxonomic in nature, Shaw having incorporated as much natural history information as he could glean from his sources, together with tales of the potency of various snake venoms and even some quotes from Latin classics and poetry (e.g., pp. 368–369). The result is far from the dry taxonomic literature that was to dominate for the next century.

This facsimile reprint of Volume Three of the General Zoology by the SSAR combines both sections under a single set of covers, and prefaces them with an extensive (96-page) introduction by Hobart Smith and Patrick David. The facsimile is of the usual high SSAR standards of printing and binding. In comparison with an original copy I examined in the University of Sydney library (a copy which is stamped Museum Zoologicum Universitatis Frid. Guil. Berolin., and which was obtained by the University of Sydney from the family of herpetologist Dene B. Fry—it carries Fry's signature and the date 26.iii.1914), the plates in the facsimile are a little darker. This has led to loss of detail on darker parts of some plates.

The Introduction begins with a brief documentation of the little that is known of Shaw's life. Initially trained in religion, he served as a parish deacon for several years, before beginning medical training. After a few years in medical practice, he was employed

by the British Museum from 1791 until his death, first as Assistant Keeper then Keeper of the Natural History collections (see also Hankel 1998). Shaw's publications were predominantly synthetic and popularist. In addition to his General Zoology and Naturalist's Miscellany series, his two other major publications were multivolume bibliographic reviews of natural history literature (Philosophical Transactions Abridged, 1809) and compilations of his public lectures (Zoological Lectures, delivered at the Royal Institution, 1809). With his attention drawn towards public education, his museum duties suffered, and opinion of his activities in the latter direction is largely negative.

The majority of Smith and David's Introduction is a thorough exploration of the identity of the more than 400 species listed by Shaw and identification of his sources of information for each taxon. Possibly reflecting time constraints in preparation, Shaw's species accounts are inconsistent in style and quality. His acknowledged sources are often abbreviated, which may not have been a problem for the contemporary reader, but creates difficulties for the modern reader. In addition to simply summarizing previous descriptions, Shaw also introduced a number of new names, both new names for previously described taxa and new species descriptions.

Because he drew extensively on an earlier literature for his new species, a literature that was also available to other herpetologists, many of his new species are junior synonyms. However, he also made use of his access to English collections unavailable to continental workers (predominantly the British Museum and Leverian Museum), and the new species he described from specimens at hand are often still recognized. Of 108 new species described by Shaw, 26 are considered to be valid by Smith and David. A few additional names (e.g., *Boa palpebrosa*, *Coluber crucifer*, *Coluber sagittatus*) are overlooked and unused senior synonyms of names in wide current use, and about 20 additional names, particularly of snakes, are not assignable to a specific taxon. A few additional species mentioned by Shaw were presented by common names only, and would not be formally named until much later. Among the 26 valid species are such well-known names as *Rana catesbeiana*, *Ambystoma* (as *Lacerta*) *maculatum*, *Geochelone* (as *Testudo*) *radiata*, *Python regius*, *Chrysopelea* (as *Coluber*) *ornatus* and *Bitis nasicornis*, and a geographic coverage of North, Central and South America (9 species), Asia (14 species) and Africa (3 species).

Smith and David's assessments are not confined to Shaw's new names. In considering the status of all names appearing in the General Zoology, they also consider the status of a number of names proposed by Linnaeus, Laurenti, Molina, and Schneider, among others.

The bibliography, presenting full citations for the identifiable literature cited by Shaw, is a tool of tremendous value, an introduction to a literature that is now difficult to trace. In SSAR tradition, it includes numerous notes on authorship, publication dates, and editions that will assist the bibliographer.

My only significant criticism is that on a number of occasions, Smith and David apply Article 23(9) of the new (1999) edition of the Code of Zoological Nomenclature to reject unused senior synonyms (not all of them Shaw's) of names in current usage. However, they do not fully abide by the requirements of this Article and its related articles. The new Article, aimed at maintaining stability of nomenclature, allows rejection of an unused senior synonym (which becomes a *nomen oblitum*) and retention of the junior synonym in use (which becomes a *nomen protectum*) without recourse to the ICZN in certain circumstances. The senior synonym must not have been used as the valid name since 1899, and the junior synonym must have been used in more than 25 works by a minimum of ten authors during the past 50 years. In invoking Article 23(9), Smith and David do not demonstrate the latter in any instance, nor do they explicitly state that the former applies. Hence their actions are not valid. This Article will undoubtedly prove a headache for editors wishing to minimize the length of papers, but these requirements must be followed in order for Article 23(9) to be applied.

This criticism apart, the SSAR edition of Shaw's General Zoology will appeal to a wide readership, from the non-specialist interested in temporarily experiencing a past world or seeking unusual illustrations, to systematists, historians, and bibliographers from a wide range of backgrounds.

Herpetofauna of West Africa vol. I: Ampibians of the West African Savanna, by Mark-Oliver Rödel. 2000. Edition Chimaira, Frankfurt am Main. 332 pp. Softcover, plus audio CD. DM.– 88 (approx. US$ 43). ISBN 3-930612-16-X.

ARNE SCHIØTZ
Humlehaven 2, DK 4571 Grevinge, Denmark
e-mail: SCHIOETZ@worldonline.dk

This book covers the fauna of frogs and toads in the savanna belt of the entire West Africa, from Cameroun and Chad westwards. It gives a careful and detailed treatment of all the species known from this area, with strong emphasis on their biology. The book is the result of the author's work in Comoé National Park, northeastern Côte d'Ivoire, where he has spent 19 months over a four year period studying tadpole ecology.

Strictly speaking the book does not cover the Amphibia, but only the Anura. Like many people, the author presumably regards the gymnophiones merely as advanced earthworms, not deserving the attention of real herpetologists!

The book is an English version of his *Amphibien der Westafrikanischen Savanna* originally published in 1996 (reviewed in Herpetological Review 28:218). Compared to the German version the text has been extended somewhat, the literature citations have been brought up to date, the quality of the black and white photos of biotopes has been improved considerably, the number

of color photos has been increased, and a CD with the voices of some frogs has been added.

The West African Amphibia fall into three distinct faunas or guilds: one connected with moist evergreen forests, another associated with savannas, and a third found in dry gallery-forests and patches of dry forest and farmbush within the savanna belt. This book deals with the two latter faunas. Somewhat confusingly, the author, in his very brief general chapter on the West African savanna belt, uses the term forest for what is conventionally called Guinea savanna. This vegetation zone is characterized by scattered trees in an otherwise grassy habitat, is subject to frequent burning, and harbors a typical savanna frog fauna.

The author mentions that this book originally was planned as a monograph of the frogs of Comoé National Park, but that the lack of accessible literature for many of the genera caused him to expand its scope. Such an extension has its advantages and disadvantages. One advantage is that a book covering the entire area is obviously far more useful than one about Comoé alone. A disadvantage is that the author's familiarity with the species necessarily must be very uneven (although fortunately, most West African savanna and farmbush species are so widespread that the majority of the forms occur in Comoé). Despite the broader scope of the book as a whole, however, the author's original plan is still evident. For example, in the introductory chapter describing the environment 12 pages are devoted to a detailed description of Comoé National Park, while West Africa as a region is given a mostly cursory description on a single page.

Rödel has used the literature exhaustively, but has used museum collections only to a very limited degree. The book is an exercise in literature extraction, to a degree that reminds one of the proverbial German thoroughness in scientific publications. Every bit of information throughout the book is followed by meticulous literature references. This makes the book very useful, but it also makes reading very bumpy and sometimes tedious. For example, the paragraph on the distribution of *Hoplobatrachus occipitalis* includes a list of the countries where the species occurs, followed by 83 references which occupy half a page! In spite of its length, such a list of references is of limited use since there is no direct link between particular countries and specific references, so if one needed to check who has recorded the species for Sudan, all of the references would need to be searched.

The sections on geographic ranges thereby are not only long and difficult to work with, but suffer greatly from the total lack of distribution maps. Such maps would have been most useful, not only to illustrate the distributions at a glance, but to provide more precision than a mere listing of countries allows.

An example of the coarseness of presenting only country records and of the danger of relying on literature without checking the actual specimens is seen in the distribution of *Afrixalus dorsalis*. According to the text, it is widely distributed not only in West Africa but also in the greater part of Central Africa, namely Gabon, Congo, R.D. Congo, Angola, and the Central African Republic. In fact the species is only found outside of West Africa in a narrow belt along the Atlantic coast from Cameroun to Angola. A map would have also shown that the record from the Central African Republic is suspiciously outside the species' range (in fact the record represents *A. vittiger*, the confusion stemming from the name *leptosomus* being variously associated with both species). Rödel does, in a note, mention the correct range of the species, but almost as an afterthought.

This raises the question of how selective one should be with distribution data, especially data from older papers for which identifications have not recently been verified. Rödel tends to accept all records, including older ones, at face value, although for some species he does use a question mark for such doubtful records. In my opinion he nevertheless includes too many records that are unchecked and therefore suspect. Museums and older publications are full of misidentified specimens. I believe that one should, especially in a non-technical book such as this, restrict rather than expand distributional data. In the Copenhagen database of distribution of African Amphibia it has thus been the policy to omit doubtful, unchecked old records, especially those on the periphery or outside of the known range.

Voices are of paramount importance for anuran taxonomy, since they are the primary species-specific characters in many groups. Sonograms and oscillograms are presented for the species Rödel has encountered in Comoé. Quite apart from the question whether oscillograms provide information not contained in the sonograms, both types of representations are reproduced so poorly that they are of very little use. This is a pity, and difficult to understand since much better sonograms of almost all the species have been published elsewhere. A CD is included with the voices of 24 out of the 51 species covered in the book, plus some "soundscapes" of Comoé N.P., compiled by Ulmar Grafe. The quality is high, but again one would have preferred that the many voices available from other workers be included. Only then would the voices have been really useful for the field worker, especially in difficult genera, such as *Ptychadena* and *Phrynobatrachus,* where species are easier to identify by voice than by appearance.

It is likewise a rather annoying peculiarity that, while the author is most keen to use all available literature, with very few exceptions he uses only his own illustrations, even when much better illustrations have been published elsewhere or in cases in which figures borrowed from other works would have made valuable additions (e.g., species not encountered by the author in the field). Had he been more willing to utilize such published illustrations Rödel could have presented sonograms of almost all species (instead of only those from Comoé) and could have provided better drawings of male throats (e.g., *Phrynobatrachus*, *Kassina,* and *Hyperolius*).

The meticulous descriptions of tadpoles, including possible differences between species in the same genera, are a valuable contribution. These descriptions include electron micrographs of mouthparts of most species as well as many observations on tadpole ecology (the subject of a separate book by the same author).

The book ends with a very informative general chapter on the biology of the anuran communities in the savanna and gallery forests in Comoé National Park and with an extensive list of literature.

In spite of criticisms expressed here of many details, Mark-Oliver Rödel's book is a very thorough and valuable contribution to the systematics and biology of the little known anuran fauna in the savanna and dry gallery-forests of West Africa. It combines a most impressive literature extraction with many original field observations from Comoé National Park.

This book represents an updated and expanded edition of *The Reptiles and Amphibians of Maine* (Hunter et al. 1992). Like its predecessor, *Maine Amphibians and Reptiles* provides a general introduction to the herpetofauna of Maine that is directed primarily toward the amateur naturalist. While the core of the book has changed little since the first edition, several new features have been added that significantly increase the book's utility for non-specialists. Regrettably, however, several aspects of the original edition that limited the book's usefulness among herpetologists remain unchanged in the new edition.

The book opens with a brief preface, followed by several short introductory chapters. The first and second chapters provide cursory overviews of the evolution, natural history, and physiology of amphibians and reptiles, respectively. Both of these chapters are rather brief (two pages each), and focus only on the most fundamental aspects of amphibian and reptile biology. The following chapter is a brief synopsis of the physical geography of Maine and its influence on the distribution of amphibians and reptiles within the state. While this chapter may be potentially useful for interpreting biogeographical patterns, I believe its utility in this capacity would be greatly enhanced with the inclusion of a topographical map of the region. The fourth chapter, dealing with conservation, details the most serious threats facing the state's herpetofauna and the steps that are being taken to counter these threats. Included in this chapter is a useful table that gives the current status of all amphibian and reptile species listed as endangered, threatened, vulnerable, or of special concern in the six New England states and five provinces of Atlantic Canada. Finally, the introductory section of the book concludes with a short chapter on finding and enjoying amphibians and reptiles, as well as a brief overview of the regional range maps that were incorporated into the new edition.

The introductory chapters are followed by a checklist of Maine amphibians and reptiles and a 16-page gallery of color photographs. In the checklist, subspecific names are given only for those species that are represented in the state by multiple subspecies. While this was presumably done to make the checklist less daunting to the non-specialist, I found this convention to be awkward and unbalanced. The color photographs represent a new and valuable addition to the book. Although the quality of the photos is somewhat variable and one (of *Nerodia sipedon*) is printed upside-down, nearly all provide a greater level of detail than that which is found in the line drawings that accompany each species account. As a result, the book is now more likely to be useful for purposes of identification.

The remainder of the book's text is devoted almost entirely to accounts of the 38 species of amphibians and reptiles that occur (or have occurred historically) in Maine, including both the introduced mudpuppy (*Necturus maculosus*) and the extirpated timber rattlesnake (*Crotalus horridus*). These accounts were contributed by 27 different authors, ranging from amateur naturalists to professional field biologists. As a result of the number of authors and their diverse backgrounds, the species accounts vary somewhat in coverage, use of references, and overall quality. This potentially distracting heterogeneity is limited to some degree, however, by the consistent format adhered to by the authors. Each account consists of six to eight sections: Description; Voice (for anurans only); Taxonomic Status (for species having multiple subspecies); Distribution and Status; Habitat; Reproduction; Diet; and Interactions with People and Other Animals. In general, the species accounts have changed little since the first edition. Most have been revised minimally to incorporate information from recent studies published between 1991 and 1998. However, the accounts of the spotted turtle (*Clemmys guttata*) and wood turtle (*Clemmys insculpta*) were contributed by new authors and have been entirely rewritten. Also new to this edition are line drawings illustrating some of the diagnostic characters useful for identification purposes for each of the four orders of amphibians and reptiles that occur in the state. While these figures are useful additions, they do not include all of the characters that are referred to in the text. For instance, the number of dorsal scale rows is given as a diagnostic character to distinguish *Storeria dekayi* from *Storeria occipitomaculata*, but the figure summarizing the external morphology of snakes neither labels the dorsal scale rows nor illustrates how to count them accurately.

In general, the species accounts provide accurate information and sufficient detail for the intended audience. However, I did notice two errors in terminology in these accounts. First, in both the description of *Bufo americanus* (p. 73) and the figure illustrating the external morphology of anurans (p. 71), the parotoid glands are referred to as 'parotid glands.' Second, in the account of *Terrapene carolina* (pp. 148–149), the upper jaws are referred to as the 'upper mandible.'

Following the species accounts is a short chapter dealing with "hypotheticals" (species that are known from nearby states or provinces but have not been documented in Maine), "accidentals" (vagrants that occur only sporadically in Maine, e.g., sea turtles), and "other oddities" (exotic species that have been found in the state but have not become established). This is then followed by a key to Maine's amphibian eggs. This key is one of the most valuable of the new additions to this book. In fact, its utility and simplicity prompted me to wonder why no key was included for adults.

The final section of the book is devoted to the geographical distributions of individual species within the State of Maine. Separate maps are provided for each species, documenting their known distributions by township according to records derived from the Maine Amphibian and Reptile Atlas Project (MARAP). Species occurrences are plotted onto the maps according to 3 or 4 different levels of verification: 1) a specimen was collected or photographed; 2) a specimen was handled, then released; 3) a specimen was seen, but not captured; and 4) a specimen was heard, but not captured (applicable to anurans only). I was pleased to see the increased size of the range maps in this new edition, which makes them much easier to read than those in the original edition. However, I was disappointed to see that many conspicuous gaps still

New

Turtle Conservation

Edited by Michael W. Klemens

Considering the most significant threats to turtles and tortoises worldwide, nineteen turtle conservation and biology experts chart the successes and failures of past conservation programs and review the outlook for the group.

8 b&w photographs, 7 b&w illus. • 344 pp. • Hardcover $35.00

Rattlesnake

Portrait of a Predator

Manny Rubio

Foreword by William S. Brown

"[Rubio] admirably achieves his goal of presenting a thorough, semitechnical introduction to rattlesnakes, thoughtfully including the exact combination of basic and supplementary information such a text should contain. . . . Rubio's many photographs are exceptional for their clarity and vivid colors as well as for their illustrative effectiveness." —*Herpetological Review*

263 color photographs • 272 pp. • Hardcover $49.95

New in Paperback

Turtles of the United States and Canada

Carl H. Ernst, Jeffrey E. Lovich, and Roger W. Barbour

"[T]his book is a monumental work. It will undoubtedly serve as the standard reference to North American turtles for the next generation of biologists. Every serious vertebrate biologist on the continent will want a copy." —*Herpetological Review*

57 color, 241 b&w photographs, 63 line drawings • 682 pp. • Paperback $29.95

Measuring and Monitoring Biological Diversity

Standard Methods for Amphibians

Edited by W. Ronald Heyer, Maureen A. Donnelly, Roy W. McDiarmid, Lee-Ann C. Hayek, and Mercedes S. Foster

Foreword by David Wake

"Anyone contemplating research on amphibians should own and read a copy of this book. Even biologists with extensive experience with amphibians will find many new ideas and approaches to research in this volume." —*Conservation Biology*

Herpetology Resources

exist in these range maps, despite the incorporation of approximately 1200 new MARAP records. This undoubtedly results both from the natural tendency to focus search efforts on rare species (often having highly restricted ranges) and from Maine's relatively low population density (the lowest of any state east of the Mississippi River). I also thought that it was unfortunate that no effort was made to incorporate distributional data from museum specimens. Despite these criticisms, however, these maps serve as useful preliminary approximations of species distributions and will hopefully motivate both amateur naturalists and professional field biologists to intensify their searches for amphibians and reptiles in Maine's less populated areas (such as central and western Aroostook County).

Given its reasonable price, I can recommend this book to nonspecialists with few reservations. New additions such as the color photographs, the key to amphibian eggs, and the included compact disc with recordings of anuran vocalizations have substantially increased the book's overall utility. While the book was not written for herpetologists, it nevertheless stands as one of the most comprehensive modern accounts of the herpetofauna of any New England state. Although herpetologists will likely find Klemens (1993) to be a more useful resource for a general account of New England's amphibians and reptiles, anyone having a specific interest in the herpetofauna of Maine should buy this book.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA.

All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 700		$400
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 700	$270

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2000 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2001 — Indiana University/Purdue University, Indianapolis, Indiana, USA, 26–30 July 2001

About Our Cover: *Atheris ceratophora*

Horned or Eyelash Bush Vipers, *Atheris ceratophora*, are small (up to 54 cm in total length), semi-arboreal snakes with highly variable coloration. Plain green, black, and yellow specimens are known. More recently, individuals exhibiting a mottled pattern of irregular black blotches or bands over yellowish ground colors have been arriving in shipments from Tanzania and Kenya.

Atheris ceratophora is known to occur only in high elevation (~1400 m) forests with abundant moisture. They are restricted to several montane "islands" of habitat in eastern Tanzania in the Usumbara and Udzungwa (=Uzungwe) mountain ranges, and possibly also those of the Uluguru Mountains (Rasmussen and Howell 1982. Amphibia-Reptilia 3:269–277). Specimens have been encountered on the ground, on low stumps, and in short bushes and tussocks of grass. Irascible when approached, they don't hesitate to strike defensively.

Their wild diet includes frogs, although imported specimens have also accepted geckos, baby birds, and small rodents readily in captivity. Captive specimens are crepuscular and nocturnal, and prefer cooler temperatures than other *Atheris* species. A temperature from 55°F (~13°C) at night and up to 75–80°F (~24–27°C) by day has proven successful for maintenance (Michael Jacobi, The World of Atheris, http://www.worldofatheris.net). Captive reproduction is unknown.

The bush vipers comprise a group of mostly small snakes endemic to Africa. Most species have narrow distributions, their ranges associated with montane islands or other disjunct habitats that have favored isolation. Fourteen species are currently recognized within the Tribe Atherini (Broadley. 1996 J. Herpetol. Assoc. Africa 45(2):40–48): 11 species of *Atheris*, and one each in the genera *Adenorhinos*, *Montatheris*, and *Proatheris*. A tuft of one to three raised supraocular scales gives *A. ceratophora* a distinct appearance, readily differentiating it from other bush vipers. While most species of *Atheris* are principally arboreal, those of the monotypic genera are typically terrestrial. Recent works by Broadley (1998. Herpetol. J. 8:117–135) and Lawson (1999. Proc. Biol. Soc. Washington. 112[4]:793–803) have added to the list of known species.

Bill Love (Blue Chameleon Ventures) used Fujichrome Velvia (ASA 50) film to capture this cover image of one of the very first 'tiger phase' specimens imported into the USA in the late 1990s. The snake was a female, part of a shipment imported from Joe Beraducci of Mountain Bird Company in Arusha, Tanzania, by Rob MacInnes of Glades Herp, Inc. of Fort Myers, Florida.

Separation and imaging of Love's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

Sherman A. Minton Student Travel Awards Call for Applications

Awards of US $200 each are available for travel to the SSAR/HL Annual Meeting, Indianapolis, Indiana, 26–30 July, 2001. An applicant for a travel award must be a student and must be first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the paper or poster abstract to be presented; and 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site are excluded from applying for a travel award.

Applications must be postmarked by 15 May 2001. Award recipients will be notified by 1 June 2001 and award checks will be disbursed at the meeting. Direct requests for information and submit applications to: *Stephen C. Richter, Department of Zoology, The University of Oklahoma, Norman, Oklahoma 73019-0235, USA. Tel: (405) 325-7671; fax: (405) 325-6202; e-mail: richter@ou.edu.*

Seibert Award Winners for 2000 Announced

The ninth annual Seibert Awards were presented at the 43rd Annual Meeting of the SSAR in La Paz. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). The awards are given in recognition of outstanding student presentations at the annual meetings. Awardees received a check for US $200 and a book from Academic Press. The winners:

Conservation: **P. M. Richards**, University of Miami, Coral Gables, "Population modeling of the American crocodile, *Crocodylus acutus*, for conservation and management in South Florida."

Systematics: **C. R. Feldman**, Department of Biology, San Francisco State University, "Molecular phylogeny of emydine turtles." (Co-author J.F. Parham).

Physiology/Morphology: **N. I. Filoramo**, Department of Ecology and Evolutionary Biology, University of Connecticut, "Ultrastructure of the lingual surface in anguimorph lizards and snakes: evolutionary and functional implications." (Co-author K. Schwenk).

Ecology/Evolution: **P. R. Stephens**, Carnegie Museum of Natural History, "The effects of phylogenetic history on patterns of emydid species richness at different spatial scales." (Co-author J J. Wiens.)

The judges were Bob Brodman, Stanley Fox, Randy Jennings, Hinrich Kaiser, Todd Reeder, Steve Secor, Lynnette Seivert, and Kelly McCoy (Chair).

Kennedy Student Award Committee Annual Report—2000

The Kennedy Award Committee has completed its work for Volume 33 of the *Journal of Herpetology*. The Committee has selected "Lizard assemblage response to a forest ecotone in northeastern Australia: a synecological approach" by **Simon D. S. Conroy** (Vol. 33:409–419). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

The Committee encourages each student member of the Society to submit their work to the *Journal*, and encourages each regular member who supervises the work of students to encourage his/her students to submit their work to *JH*.

SSAR Student Travel Awards Call for Applications

Awards of US $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award.

APPLICATIONS MUST BE POSTMARKED BY 15 MAY 2001. Award recipients will be notified by 1 June 2001 and award checks will be disbursed at the meeting. Direct requests for information to: *Scott Boback, 331 Funchess Hall, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849-5414, USA; e-mail: bobacsm@auburn.edu.*

SSAR Student Awards Fund-raiser: 2000 Results and Call For 2001 Donations

Thanks to the many generous donations from several individuals to the 2000 silent auction at La Paz, the SSAR Student Travel Awards Committee (SSAR STAC) awarded seven US $200 travel grants to the following individuals: Scott Boback, Felipe Rodriguez, Nicole Gerlanc, Norma Manriquez, Michael Shapiro, Patrick Stephens, and Omar Torres-Carbajal. The SSAR STAC wishes to thank all who donated items to the 2000 silent auction at La Paz: United Design, David Hardy, Julian Lee, Rainforestimages.com, AVM/Barbara Kermeen, William Montgomery, Breck Bartholomew, Scott Boback, Roy McDiarmid, Hobart Smith, Roger Birkhead, Jackie Grant, Chris Scott, Henry Mushinsky, Biomark, Norm Scott, Al Savitzky, Smithsonian Institution Press/Vincent Burke, Dick Vogt, Rudy Ruibal, Wade Sherbrooke, Ken Dodd, Laurie Vitt, Jan Caldwell, and Peter Uetz. The sixth annual Frameable Art Silent Auction raised over US $2065 for future student travel awards. On behalf of the SSAR, thanks to all who helped, including Lynda Richter, Mark Walvoord, Cari Deen, and the La Paz meeting organizers. Special thanks for a job well done to the SSAR STAC Chairman, Stephen Richter.

The SSAR STAC announces the Seventh Annual Frameable Art Silent Auction to be held at the 2001 SSAR meeting at Indianapolis. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *Scott Boback, 331 Funchess Hall, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849-5414, USA; e-mail: bobacsm@auburn.edu.*

Amphibian Population Declines Symposium

Since the problem of amphibian population declines became known just over ten years ago, an enormous and productive international research effort has ensued, mobilized to a considerable extent around the world by the Declining Amphibian Populations Task Force. From a worrisome notion ten years ago, it is now abundantly recognized that amphibian populations are in worldwide decline and that there are numerous causes, some hitherto unsuspected, for both the decline of numbers of individuals and the losses of populations. The imminent loss of the species they work on is the single greatest problem for amphibian biologists today.

In view of the great amount of research work that lately has been focused upon amphibian populations, now is the right time to hold an international symposium to bring together what we have learned, to discuss that new knowledge, and use it as a springboard to further understanding. With this in mind, the DAPTF last year decided to mark the end of its IUCN mandate with a major symposium on global amphibian declines.

The symposium will be held at the joint SSAR/HL herpetology meetings in Indianapolis in July 2001, with the support of both societies and DAPTF. David M. Green and Karen Lips are the organizers. The symposium will be a singular and seminal event. It will be a significant synthesis of information on declining amphibian populations, with implications for the conservation biology of herpetofauna in general.

The symposium tackles a global issue and speakers will be coming from distant corners of the world, including countries where a plane ticket to Indianapolis is beyond their means. To make this event a success, we ask for your help. The DAPTF, in conjunction with HL and SSAR are doing everything they can to be able to provide these eminent researchers with the funding to attend and speak. US $1500 will sponsor one overseas speaker. SSAR will accept your tax-deductible (for US residents) contributions in support of the symposium. Donations should be directed to: *Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA; e-mail: ssar@slu.edu.*

2000 Annual Meeting: La Paz

The 43rd annual meeting of SSAR took place from 14 to 21 June 2000 in La Paz, Baja California Sur, Mexico. This year's meeting was held jointly with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists and was hosted by the Universidad Autónoma de Baja California Sur. Herpetological presentations were conducted at the Hotel Araiza Inn Palmira, a very pleasant location. In being marginalized by the ichthyologists on the planning committee, SSAR members were ensured cultural opportunities not experienced by our fin-bearing brethren; casual sea-side walks, stimulating conversation with local taxi drivers, and herpetological excursions among the hills were all potential benefits at the Hotel Araiza. Carlos Villavicencio Garayzar served as the local chair for the meeting that saw the scheduled presentation of 968 talks and posters. Armed guards at the airport and lost luggage aside, the meeting was a terrific success.

Social Programs

Numerous social events served as diversions from the lively discussions of the daily scientific sessions. On Wednesday, 14 June 2000, an informal "no-host" social saw many herpetologists and ichthyologists rubbing elbows at Carlos and Charlie's, a watering hole and eatery in downtown La Paz. The Opening Plenary Session, on the surprisingly rainy morning of 15 June, kicked off with an introduction by Local Committee Chair Carlos J. Villavicencio Garayzar. Joint Meeting attendees were given a warm welcome by C. Leonel Cota Montaño, the Governor of Baja California Sur. The Governor stated that attendees were always welcome to return to La Paz if we brought significant precipitation, the first the region had seen in over two years. The Herpetologists' League Distinguished Lecture was given by Linda Trueb, who spoke on "Frogs, fossils and phylogeny: a perspective on the last 140 million years and prospectus for the future." José Luis Castro Aguirre gave an historical ichthyological presentation that focused on the contributions of Mexican scientists to the field. Herpetologists and ichthyologists, alike, were able to appreciate the humor and insight of ASIH Past President Robert Cashner's address, one that had attendees rolling in the aisles of the Teatro de la Ciudad. Scientific sessions commenced after a lunch break that followed the obligatory photographs of meeting attendees.

The Muelle Turístico served as the venue for the Joint Meeting Reception on the evening of 15 June 2000. Attendees were greeted by smiling representatives of the Cervecería Tecate, who supplied ample quantities of their products for consumption. Many of the resort hotels sponsored tents that provided a generous mix of local cuisine offerings. Music and spirits filled the air as the sun set over the Sea of Cortez and social adventures continued into the night. The Graduate Student Reception on 16 June was held at El Kiosko in downtown La Paz. Certainly, the highlight of the social events for the Joint Meeting was the Beach Picnic at Playa El Caimancito, the Governor House, on Saturday, 17 June. A great variety of delicious seafood and beverages were consumed as the waves splashed at the heals (and other body parts) of attendees. Live music provided a poolside alternative to those not exploring the sea life of the breakwater.

The SSAR Auction was held on the evening of 18 June in the Loreto Meeting Room of the Hotel Araiza Inn Palmira and was conducted by David Morafka. A cash bar, supplemented by free drinks tickets handed out by President Lee, helped to stimulate aggressive bidding for a number of exceptional auction items. An item of particular note was an antique African beadwork hanging loaded with herpetological iconography and symbolism that saw hefty bidding action. The evening of Monday, 19 June, saw numerous guests taking part in a dinner and "roast" to honor Jay Savage and his contributions to herpetology. The social events of the Joint Meeting closed on 20 June with the reception and banquet sponsored by the attending societies. This event was hosted at the Crowne Plaza, a lovely facility that overlooked the Sea of Cortez. Finally, many post-meeting field trips offered the possibility for natural history excursions and explorations including trips to nearby islands to view endemic herpetofauna and snorkeling with schools of hammerhead sharks. Even the hillside above the meeting location held a unique assemblage of organisms for those adventuresome souls who chose to explore the xeric habitats of La Paz.

Business Meeting

Society President Lee called the Annual SSAR Business Meeting to order at 1611 h in the Pescador Room of the Marina Hotel on 17 June 2000. Approximately 20 Society members were in attendance, most of these being members of the Board or holding other Society positions.

Julian Lee summarized the Presidential Report to Board of Directors by focusing on two key issues: 1) recruitment of new members to the Society, and 2) the appointing or resignation of Board Members and publications editorial staff. Membership continues to remain stable, but could draw from additional areas within the herpetological community (i.e., zoological park and state/federal agency personnel). During his term, President Lee appointed (with Board approval) the following individuals to positions within the Society. A) Michael V. Plummer – Chair of the Conservation Committee. Plummer will head an eight-member committee that in-

Meeting attendees enjoyed a beach picnic at Playa El Caimancito, the Governor's House.

cludes Kurt Buhlmann, Ken Dodd, Mike Dorcas, Lee Fitzgerald, John Jensen, Andy Price, Steve Sheffield, and Mike Sredl. President Lee praised Plummer for his aggressive coordination of the committee and energetic revitalization of the Conservation Committee. B) Aaron Bauer – Editor of *Facsimile Reprints in Herpetology* beginning January 2002 (to replace Kraig Adler). C) Brian K. Sullivan – Editor of the *Journal of Herpetology* beginning January 2001 (to replace Richard Seigel). D) Ms. Jean Bann – hired as copy editor for the *Journal of Herpetology*. Additionally, President Lee has accepted the resignation of Harold Dundee as Caudata Editor for the *Catalogue of American Amphibians and Reptiles*. All outgoing editors and officers are thanked for their thoughtful service to the Society.

President Lee announced the establishment of a one-time, multiple person award in memory of the late Sherman A. Minton, M.D. that would serve to recognize his many contributions to herpetology, toxicology, and medicine. The Sherman A. Minton Student Travel Awards (SM-STA) will be made to approximately ten students and will serve to defray the costs of attending the annual meeting in Indianapolis in July 2001. A minimum goal of US $2000 is expected to be raised and will be allotted to students in the range of US $200–$400 to individuals presenting at the meeting. David Hardy will chair the SM-STA committee and Stephen Richter will help to implement the selection process.

Society Treasurer Robert Aldridge reported that SSAR remains financially viable with total assets of $219,000 in restricted accounts. Aldridge reported that the sale of Joseph Bailey's library collection grossed $20,620 for the Society. Lee thanked Kraig Adler and Steve Busack for their roles in the sale of the Bailey library. Bob Aldridge changed hats and reported, as the Publications Secretary, that the Society has a collection of publications valued at $500,000. He stressed the importance of decreasing the current holdings as they represent potential revenues for the Society. President Lee announced that Aldridge has tendered his resignation as Treasurer (to take effect at the end of 2001), but will remain as Publications Secretary. Bob Aldridge and wife, Linda, were praised for the job they have done for the Society and President Lee stressed the need for a replacement for this important position.

Herpetologists enjoyed a unique dining experience at Playa El Caimancito.

Jay Savage was this year's recipient of the Henry Fitch Award, presented by Harry Greene. The Fitch Award was initiated by ASIH in 1998 to recognize excellence in the field of herpetology. A "Savage Symposium," featuring talks in tropical ecology and evolution, spanned two days of the meetings, and Savage was also honored at an evening dinner and roast.

Outgoing *Journal of Herpetology* Editor, Rich Seigel (*in absentia*), submitted a report indicating a number of personnel changes. Brian Sullivan has assumed the duties of Editor as of August 2000. Additional changes in the editorial staff include John Fauth (Associate Editor), Brent Graves (Associate Editor), and Dawn Wilson (Editorial Board). Rich reported that submissions to the *Journal* were down slightly in 1999 from the previous year, but still remained solid at 235. Submissions as of May 2000 were running higher than a comparable date in recent years, and could reach record levels. To this point, the *Journal* has been able to maintain a backlog time of no more than 12 months thanks, in part, to an increase in the publication budget for 1999, a lower submission rate for the same period, and reduced publication costs from Allen Press. Seigel cautions that the backlog time for accepted submissions could increase as the average submission increases in length (from 5.5 pages/title in 1997 to 6.3 in 1999) and the need for additional funds for publication charges persists. Lastly, Seigel noted that the addition of a Copy Editor for the *Journal* will aid in journal production, but will incur a cost to the Society.

Herpetological Review Editor, Robert Hansen, reports personnel changes including new Associate Editors Gunther Köhler, Brad Hollingsworth, Adam Summers, and Michael Dorcas. New Section Editors include Winston Card (Herpetological Husbandry), Travis Ryan (Legislation and Conservation), and Jennifer Garrison (Current Research). *Herp Review* seems to be able to maintain its current, expanded production size – 256 pages in four issues for Volume 30. Bob reports that the publication will be produced on glossy paper stock beginning with Volume 31. He also announced the addition of a new section within *HR*, Herpetological History.

Robert Powell (*in absentia*), Editor of the *Catalogue of American Amphibians and Reptiles* (*CAAR*), submitted a report on the status of this important publication effort. Bob reports that the

1999 contributions to *CAAR* consisted of 20 accounts (Nos. 681–700; 8 salamander, 1 frog, 2 turtle, 6 lizard, 2 snake, and 1 crocodilian accounts)—for a total of 97 printed pages. Color plates were included in 16 of the accounts. Bob expects the completion of 20 accounts for 2000, has plans for another 20 accounts for 2001, and would like to see this number maintained annually, as long as sufficient number of individuals submit species accounts. Digital technology is being used to archive *CAAR* accounts on CD-ROM.

Kraig Adler, Editor (*in absentia*), submitted reports on the activities of two Society publication series, *Contributions to Herpetology* and *Facsimile Reprints in Herpetology*. Recent publications include "Lizards of Iran," by Steven Anderson (1999) and "General Zoology: Volume 3 Amphibia," by George Shaw (1999). Upcoming and newly completed offerings include several significant publications. "Herpetological Illustrations from the Spencer Research Library, University of Kansas," compiled by Sally Haines is scheduled for fall 2000 and will feature the development of herpetological illustration from 1550 to 1950. "Herpetofauna of New Caledonia and Surrounding Islands," by Aaron Bauer and Ross Sadlier is expected in late 2000. William Duellman has updated his classic 1970 publication, "Hylid Frogs of Middle America," and this should be available in late 2000. Inclusion of newly described species and original artwork by David Dennis is certain to make this a big seller. "Amphibians of Honduras," by James R. McCranie and Larry David Wilson should be published in early 2001. Also expected in 2001, is a reprinting of "Anatomy of the Salamander," by Eric T. B. Francis. Originally published in 1934, this work will have a new introduction by James Hanken. Adler reports that three additional projects are in the works and should see publication in the next year or two. These include "Field Guide to Amphibians and Reptiles of the West Indies," by S. Blair Hedges, "Lizards of Southern Africa," by William Branch and Aaron Bauer, and "Biology of the Reptilia, Volume 20 (Morphology)," edited by Carl Gans and Abbot Gaunt.

Herpetological Circulars Editor, John Moriarty (*in absentia*), submitted a report on the status of three publications in that series. *Herpetological Circular No. 27* – "Lineages and Histories of Zoo Herpetologists in the United States," by Winston Card and James B. Murphy was published in February 2000. *HC No. 28* – "State and Provincial Amphibian and Reptile Publications for the United States and Canada," by John Moriarty and Aaron Bauer is currently available. "Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding," (*HC No. 29*) by Brian Crother et al., is anticipated shortly and should be larger than previous versions of this publication.

Stephen Corn, Editor of *Herpetological Conservation* reported that progress on Volume 2, "Ecotoxicology of Amphibians and Reptiles," had been slowed, but he still anticipates its completion by the end of 2000. A proposed Volume 3, "Conservation and Status of Reptiles in Canada," has received solid backing by The Canadian Amphibian and Reptile Conservation Network. This volume will be edited by Carolyn Seburn and Christine Bishop and feature 15 chapters authored by numerous prominent Canadian herpetologists. Other projects are in the planning phase, but will require the direction of another editor as Steve Corn has requested a replacement be identified for *Herpetological Conservation*.

Several outstanding student projects received recognition during the past year. Robert Gatten reported that the Kennedy Award Committee selected the best student paper for publication in volume 33 of the *Journal of Herpetology* for 1999. The committee selected a paper authored by Simon D.S. Conroy titled, "Lizard assemblage response to a forest ecotone in northeastern Australia: a synecological approach." The ninth annual Seibert Awards were selected from student presentations made at the 43rd Annual Meeting of the SSAR in La Paz. Committee Chair C. Kelly McCoy announced the following Seibert Award winners for 2000: C. R. Feldman (San Francisco State University) – Systematics, "Molecular phylogeny of Emydine turtles," I. F. Nirvana (University of Connecticut) – Physiology/Morphology, "Ultrastructure of the lingual surface in anguimorph lizards and snakes: evolutionary and functional implications," P. M. Richards (University of Miami) – Conservation, "Population modeling of the American crocodile *Crocodylus acutus* for conservation and management in South Florida," P. R. Stephens (Carnegie Musuem of Natural History) – Ecology, "The effects of phylogenetic history on patterns of emydid species richness at different spatial scales."

Henry Mushinsky clarified many aspects of the 2001 Annual Meeting that will see SSAR meeting jointly with The Herpetologists' League at the Double Tree conference center in Indianapolis, Indiana. The meeting is scheduled for 26–30 July 2001 and will be jointly hosted by Purdue University and Indiana University. Many aspects of the 2001 meetings will serve to honor the late Sherman A. Minton, M.D., for his years of dedication to the Society and contributions to the field of herpetology. A symposium titled "Herpetological Research in Zoos: The Academic Connection" is being organized by John Groves and Hugh Quinn, and will be dedicated to Sherman Minton. David Green and Karen Lips are organizing another symposium on amphibian population declines. Other activities planned for the 2001 meeting include the beautiful herpetological imagery of David Dennis and Eric Juterbock. President Lee announced that he and Marty Crump would reinstate the Herpetology Quiz. Mushinsky stressed the need for organizational help with the meeting, especially the Society Auction—any interested individuals should contact Henry. Mushinsky also emphasized the need for graduate student projectionists for the scientific sessions, as the cost to the Society for "professional" projectionists will be excessive. When asked about the possibility of inexpensive housing (=university dormitories), Mushinsky stated that there was none available in association with the meeting site. Henry went on to say that there were few "hidden" costs connected with next year's event—registration fees will cover most of the associated social events. Mushinsky outlined possible future meeting locations including Kansas City (2002 – joint meeting with ASIH), San Diego (2003), Oklahoma (2004 – to commemorate the 20th anniversary of the joint meeting hosted by Past President Vic Hutchison at the University of Oklahoma), Tampa (2005 – to be hosted by Henry Mushinsky), and Victoria, B.C. (2006 – to be hosted by Pat Gregory).

Akira Mori summarized the results of an opinion survey he conducted of non-US members as to their satisfaction with the activities of SSAR. Mori pointed out that, at 446 individuals, non-US members account for nearly 30% of the Society's membership. He received responses from only 34 non-US members, but concluded that most comments were generally favorable. Many con-

structive comments centered on aspects of increasing international involvement and decreasing the cost to members from developing countries. The language barrier contributes to aspects of dissatisfaction from non-US members, both in terms of publication issues and communication of Society activities. Related to increasing international activities, President Lee commented on the Society's role in sponsoring a Cuban herpetologist. Associated with increased international outreach, Lee accepted an offer from Karen Lips to serve as the new Chair of the Society's International Cooperation Program (a position previously filled by Martha Crump).

On behalf of George Pisani (*in absentia*), President Lee addressed aspects of the Society webpage and electronic publishing. Pisani reported that the Society website continues to experience active visitation and is linked to many resource locations. The SSAR website was relocated from Pisani's personal directory to a dedicated location on the University of Kansas computing network. At the present time, the Society has chosen not to go "online" in terms of journal publishing. Questions of web-based membership renewal have also been explored, but deferred to a later date until aspects of security can be ensured. Pisani reports that time needed to compile corrections to the *Directory of Herpetologists* has eclipsed the abilities of the editors of that effort—Pisani, Harold Dundee, and Robert Aldridge. Members of the SSAR Board agreed that, while valuable, changes to the *Directory* would not be implemented by the Society.

Bill Cooper (*in absentia*) reported as Chair of the Publications Task Force. Of recent concern to the Task Force are issues associated with the Society's policy on institutional approval connected to the use of live animals in research. Several editorial policies address issues of the humane and ethical treatment of animals in association with field and laboratory studies. Cooper noted that Society publications require a cover letter indicating that authors have complied with all applicable institutional animal care guidelines, and that all required permits for research, collection of specimens, import, and export have been obtained in the appropriate countries. While the Task Force feels it is important for all scientists engaged in animal research to acquire appropriate permits, it is not necessary for authors submitting manuscripts to supply permit documentation. Use of museum accession numbers for voucher specimens is recommended only for those studies that are systematic in nature. Lastly, in keeping with the need for manuscript uniformity and editorial continuity, the Task Force recommends the hiring of a Copy Editor for the *Journal of Herpetology* (a recommendation that has been implemented by the Board).

Finally, in a ceremony shrouded in honor and mysticism, President Lee passed the totem of presidential office to President-Elect David Green. Green accepted the post and its scepter, laden with herpetological iconography, graciously, before the meeting was adjourned. The coming year holds much potential for the Society, as David Green becomes the first president to face a two-year term of office.

—Respectfully submitted by John M. Matter, Secretary

2000 Resolutions

Honoring Outgoing SSAR Officers, Editors, and Others

WHEREAS, the following individuals have given freely of their time, skills, and knowledge to the Society for the Study of Amphibians and Reptiles this past year; and,

WHEREAS, they have therefore been instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

WHEREAS, SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them for their fine efforts in its behalf; therefore,

BE IT RESOLVED that the Society for the Study of Amphibians and Reptiles offers its sincere gratitude to the following persons who have served in these capacities:

ROGER A. ANDERSON — Associate Editor, *Journal of Herpetology*
DANIEL D. BECK — Associate Editor, *Herpetological Review*
JERRERY P. DEMUTH — Section Editor, *Herpetological Review*
R. WAYNE VAN DEVENDER — Director
MAUREEN DONNELLY — Liaison for 2000 Local Committee
HAROLD A. DUNDEE — Editor - *Combined Directory of Herpetologists*; Section Editor — Caudata, *Catalogue of American Amphibians and Reptiles*
RENEE FERACHI-SIMS — Editorial Assistant, *Journal of Herpetology*
STANLEY FOX — Liaison for 2000 Local Committee
VICTOR H. HUTCHISON — President
MICHAEL W. KLEMENS — Conservation Committee
ANNE M. MAGLIA — Section Editor, *Herpetological Review*
LANCE McBRAYER — Student Travel Awards
LYNDON A. MITCHELL — Section Editor, *Herpetological Review*
HENRY R. MUSHINSKY — Long Range Planning, Nominating Committee
CHARLES W. PAINTER — Director
GEORGE PISANI — *Catalogue of American Amphibians and Reptiles; Combined Directory of Herpetologists*
JAY STAUFFER — 1999 Local Committee
RICHARD VOGT — Liaison for 2000 Local Committee

BE IT FURTHER RESOLVED that the SSAR urges these persons not to become consumed by other more pressing but perhaps more interesting responsibilities, but to be available in the future as resources for those who follow in their service to the Society.

Adopted by the Society for the Study of Amphibians and Reptiles, 17 June 2000, at its Annual Business Meeting.

Resolution Thanking Ellen J. Censky

WHEREAS, Ellen J. Censky has been one of the most hard-working members of SSAR for many years; and,

WHEREAS, Ellen answered the call to assist the Society by as-

suming the demanding role of Secretary, and has most capably filled this role these several years; and,

WHEREAS, the role of Secretary encompasses not only myriad tasks associated with the functioning of the Annual Meeting, but also involves guiding the President and Directors through many issues that span more than a single year; and,

WHEREAS, the Secretary thus provides needed continuity through the terms of other officers; therefore

BE IT RESOLVED that the Society for the Study of Amphibians and Reptiles here expresses its most sincere thanks to Ellen J. Censky for her dedication and service as Secretary; and be it further

RESOLVED that the Society wishes her all the best in her new professional challenges.

Adopted by the Society for the Study of Amphibians and Reptiles at its Annual Business Meeting, 17 June 2000.

NEWSNOTES

Greene and Shine Named Wilson Award Winners

Herpetologists Harry Greene (Cornell University) and Richard Shine (University of Sydney) were this year's recipients of the E. O. Wilson Naturalist Award. This prestigious award was presented at the American Society of Naturalists annual meeting in Bloomington, Indiana in June. In recognition of the lifetime of outstanding contributions of Professor E. O. Wilson in the areas of ecology and evolutionary biology, the award was established in the year of Professor Wilson's retirement from Harvard University. The Wilson Award is given to an active investigator in mid-career who has made significant contributions to the knowledge of a particular ecosystem or group of organisms. Congratulations to Harry and Rick for this outstanding recognition.

Field Museum Herpetological Collection Online

The website for the retrieval of information on the approximately 265,000 specimens in the collection of the Division of Amphibians and Reptiles at the Field Museum can be queried at http://www.fmnh.org/herps/. This new service was implemeneted as aprt of a grant from the National Science Foundation.

The Field Museum's amphibian and reptile collection is global in origin and almost equally divided between the New World and Old World. The approximate breakdown of collection holdings by major geographic area is: North America (32.9% of catalog entries), Indo-Australia (20.9%), Asia (15.4%), South American (10.4%), Africa (9.0%), Central America (4.7%), Australia (2.7%), Caribbean (1.2%), Pacific (0.9%), Europe (0.6%), Madagascar (0.5%), Atlantic Ocean (0.3%), and Indian Ocean (0.1%).

The total number of catalog entries from the United States is approximately 50,500. States representing from five to ten percent of this total include (ranked highest to lowest): Illinois, New York, Texas, North Carolina, Mississippi, and Indiana.

The collection contains over 6,000 species and 1,180 genera. The approximate breakdown of collection holdings by order or suborder is: frogs (42.6% of catalog entries), salamanders (12.4%), caecilians (0.25%), turtles (1.97%), rhynchocephalians (0.006%), lizards (26.4%), snakes (16.0%), amphisbaenians (0.16%), and crocodilians (0.26%).

Please direct any comments, suggestions, or problems to Harold Voris (e-mail: hvoris@fmnh.org) or Alan Resetar (e-mail: aresetar@fmnh.org), Division of Amphibians and Reptiles, Field Museum of Natural History, 1400 South Lake Shore Drive, Chicago, Illinois 60605-2496, USA.

Southwestern Research Station Positions And Grants For 2001

VOLUNTEERS—Approximately 30 volunteer positions are open in 2001 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024-5192, USA; http://research.amnh.org/grants/index.html; e-mail: rnavarro@amnh.org. Application due date: February 15, 2001. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632, USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reserva-

tions, answering phones, greeting guests, supervising volunteers, etc. Begin March 15, 2001, through September 2001 (end date flexible). Five-day week; salary $245/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

MEETINGS

IHS Announces Grants Program and Call for Papers

A herpetocultural/herpetological Grants Program has been established by the International Herpetological Symposium and was announced at the 24th Annual Meeting held in New Orleans, Louisiana, 19–22 July 2000. The goal of the program is to award funds to a wide variety of applicants whose projects represent a significant contribution to herpetoculture in one of the following categories: Herpetological Natural History, Herpetological Conservation Biology, Captive Propagation, and Herpetological Education. Enthusiastic amateurs will receive the same level of consideration as professional herpetologists and graduate students. For more information about the program, write to: International Herpetological Symposium, Grants Program, P.O. Box 16444, Salt Lake City, Utah 84116-0444, USA.

The 25th Annual IHS Meeting will be hosted by the Detroit Zoological Institute in Detroit, Michigan, USA, 14–17 July 2001. Individuals wishing to present their papers on herpetological natural history, conservation biology, veterinary medicine, or captive husbandry topics may submit them to Donal Boyer, Curator of Herpetology, Zoological Society of San Diego, P.O. Box 120551, San Diego, California 92112, USA.

Detailed information about the Grants Program and the 25th Annual Meeting can be found online at http://www.kingsnake.com/ihs.

Meetings Calendar

22 February 2001—Declining Amphibian Populations in California and Nevada: Causes and Solutions. Radisson Hotel, Sacramento, California, USA. This workshop will be held in conjunction with the annual meeting of The Wildlife Society, Western Section (www.tws-west.org), and is sponsored by the California-Nevada Working Group of the Declining Amphibian Task Force (DAPTF), Species Survival Commission, World Conservation Union (IUCN). For information contact: David F. Bradford, US Environmental Protection Agency, National Exposure Research Laboratory, 944 East Harmon, Las Vegas, Nevada 89119, USA; Tel: 702-798-2681, FAX: 702-798-2692, e-mail: bradford.david@epa.gov.

24–28 February 2001—21st Annual Symposium on Sea Turtle Biology and Conservation, Philadelphia, Pennsylvania, USA. Information at www.seaturtle.org.

16–19 March 2001—Desert Tortoise Council 26th Annual Meeting and Symposium, InnSuites Hotel and Resort, Tucson, Arizona, USA. Information at www.deserttortoise.org.

14–17 July 2001—International Herpetological Symposium 25th Annual Meeting, Detroit Zoological Institute in Detroit, Michigan, USA. *Refer to meeting announcement above for details.*

16–20 July 2001—Societas Europaea Herpetologica 11th General Meeting, Slovenia. Details from: DPPVN/DAPTF Slovenia, Ptujska c. 91, SI-2327 Race, Slovenia; fax: +386 (0)2 788 30 51; e-mail: milan.vogrin@guest.arnes.si.

26–30 July 2001—44th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League (http://www.inhs.uiuc.edu/cbd/HL/HL.html). Indiana University/Purdue University, Indianopolis, Indiana, USA. Details available in March 2001 issue of HR and on the SSAR web site: www.ukans.edu/~ssar/an-mtng.html.

19–23 September 2001—Association of Reptilian and Amphibian Veterinarians, Eighth Annual Conference, Orlando, Florida, USA. Details from: Charles J. Innis, VMD, VCA Westboro Animal Hospital, 155 Turnpike Road, Westboro, Massachusetts 01581, USA; tel. 508-366-1444; fax 508-634-6997; e-mail: clemmys@aol.com.

2–9 December 2001 (note change of dates)—Fourth World Congress of Herpetology, Colombo, Sri Lanka. Details from: 4WCH Promotions Office, 95 Cotta Road, Colomba 8, Sri L*anka; e-mail: admin@4wch.com; http://www.4wch.com.

LEGISLATION & CONSERVATION

Call for information on the status of amphibians and reptiles. This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. We are in need of information at local, state, national, and international levels. Please direct all communications to the section editor, Travis Ryan (postal and e-mail addresses on inside front cover).

USA: Department of the Interior: On 4 November 1997, the northern population of the bog turtle (*Clemmys muhlenbergii*) was listed as a threatened species under the 1973 Endangered Species Act (ESA). The northern population is distributed among Connecticut, Delaware, Maryland, Massachusetts, New Jersey, New York, and Pennsylvania. The ESA requires that a recovery plan be established for each listed species. A draft of the bog turtle recovery plan has been produced by the Fish and Wildlife Service and is available for the public review.

Bog turtles require a diversity of microhabitats, including wetlands and associated open canopy upland areas. The thrust of the draft recovery plan is to preserve approximately half of the current extant populations in the long-term by understanding population dynamics as well as eliminating habitat fragmentation and illegal trade.

A copy of the draft recovery plan can be obtained at the addresses below. For further information, contact: Carole Copeyon, US Fish and Wildlife Service, Pennsylvania Field Office, 315 South Office Street, Suite 322, State College, Pennsylvania 16801, USA. Also, contact Herp Digest (attn: Allen Salzberg) via e-mail at x5245@erols.com.

USA: Department of the Interior: The US Fish and Wildlife Service has proposed designating more than 2,175,000 acres of land distributed among 24 counties in central California as critical habitat for the California Red-legged Frog (*Rana aurora draytonii*). This action is designed to maintain connectivity of breeding ponds and surrounding upland habitats in an effort to stave off further fragmentation of the landscape. If the action receives final approval, land within the critical habitat cannot be adversely modified or destroyed by any activities funded or authorized by any federal agencies or persons. The call for comments ended 11 October 2000. For further information, contact: Curt McCasland or Brian Twedt, US Fish and Wildlife Service, Sacramento Fish and Wildlife Office, 2800 Cottage Way, W-2605, Sacramento, California 95825-1864, USA.

USA: Department of the Interior: On 21 September 2000, the US Fish and Wildlife Service listed the Santa Barbara County Distinct Vertebrate Population Segment (DPS) of the California Tiger Salamander (*Ambystoma californiense*) as endangered under the 1973 Endangered Species Act. In order to be considered for protection as a DPS the candidate population must be found to be a discrete population segment (relative to the rest of the species distribution) comprising a significant portion of the population. Genetic analyses suggest that there are low levels of interchange among the Santa Barbara County DPS and the rest of *A. californiense*. Five of six habitat complexes within the range of the DPS have undergone serious degradation (conversion to vineyards, grazing land) in the last several years, with plans for more habitat conversion pending at the time of listing.

The listing completes a long series of federal conservation actions. *Ambystoma californiense* was first listed as a candidate species (category 2) in 1985. In 1992 the Fish and Wildlife Service was petitioned to list the species, but this did not result in federal protection. The current ruling is the result of an emergency rule published 19 January 2000. See *Herpetological Review* 31:68 for further details. For further information, contact: Grace McLaughlin, Ventura Fish and Wildlife Office, 2394 Portola Road, Suite B, Ventura, California 93003, USA.

USA: Department of the Interior: The US Fish and Wildlife Service has designated more than 400,000 acres as critical habitat for the Alameda Whipsnake (*Masticophis lateralis euryxanthus*). The habitat designation makes it illegal for Federal agencies and their charges to destroy or damage the critical habitat that is distributed among several California counties (Contra Costa, Alameda, San Joaquin, and Santa Clara). See *Herpetological Review* 31:67 for further details or contact Jason Davis or Heather Bell, U.S. Fish and Wildlife Service, Sacramento Fish and Wildlife Office, 2800 Cottage Way, Suite W-2605, Sacramento, California 95825, USA.

International: World Conservation Union-International Union for Conservation of Nature and Natural Resource (IUCN). The recently released 2000 Red List of Threatened Species shows an increase the number of reptiles listed since the 1996 of the list. The current edition lists 291 species as Critically Endangered, Endangered, or Vulnerable, up from 253 four years ago. The 2000 list includes 24 Critically Endangered and 47 Endangered species. The crisis over freshwater turtles in Southeast Asia (see *Herpetological Review* 30:68–69) is largely responsible for the increase. The IUCN lists habitat loss/degradation, unsustainable use (exploitation), and invasive species as the major causes of the worldwide loss of biodiversity. For more information, contact: IUCN Red List Programme Office; e-mail: craig.hilton-taylor@ssc-uk.org, website: www.iucn.org.

USA: New York: On 23 August 2000, New York governor George Pataki signed into law a bill that requires posted signs warning of the risk of salmonellosis that is associated with handling reptiles. The signs are to be posted in all pet stores and other retailers trading in reptiles within the state. Failure to comply carries a maximum fine of US $500. The law is due to take effect in February 2001. For more information, contact: Herp Digest (attn: Allen Salzberg) via e-mail at x5245@erols.com.

USA: US Senate: On 20 September 2000, the United States Senate ratified the Inter-American Convention for the Protection and Conservation of Sea Turtles. The US is one of eight countries in the Americas entering into the treaty that will require 1) the use of turtle excluder devices in trawl nets used in shrimping, 2) protection of nesting beaches and other sea turtle habitats, and 3) prohibit the international trade of sea turtles and sea turtle products. The treaty further supports research efforts into sea turtle biology and conservation. For more information, contact: Amanda Johnson, National Wildlife Federation; telephone: (202) 797-6801.

CURRENT RESEARCH

Please refer to Volume 31, Number 1 for information concerning submissions to this section. Section editor contact information is located on the inside front cover of this issue.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Blindness Not Detrimental to Island Snakes

Researchers working on Carnac Island, Australia, found many adult tiger snakes in the study population to have suffered from injuries which resulted in the snakes' partial or total blindness. Behavioral and mark-recapture data were utilized to determine the effects of these injuries on survival and fitness of the snakes in relation to their uninjured counterparts. While it is often assumed that all organ systems must be functioning in a study organism for optimal survival, the researchers recorded some counterintuitive observations. The survival (as measured by recapture rate) of blind snakes was higher than in uninjured snakes, while body mass increase, growth rate (SVL), and body condition (ratio of mass to SVL) were unaffected by blindness. In addition, two blind male snakes were observed trailing and subsequently mating with female snakes. The plasticity of visual systems in snakes along with

these observations begs the question, "What factors may permit the loss of sight without negative effect?" The authors suggest that the low predation pressure imposed on this introduced population along with a rich food source (a gull rookery) are contributing factors. In addition, their findings lend support to the hypothesis of "momentarily excessive construction" presented by Gans. According to this theory, organisms may posses complex sets of features not required for survival and reproduction. In essence, organisms may be "overdesigned."

BONNET, X., D. BRADSHAW, R. SHINE, AND D. PEARSON. 1999. Why do snakes have eyes? The (non-)effect of blindness in island tiger snakes (*Notechis scutatus*). Behavioral Ecology and Sociobiology 46:267–272.

Historical Biogeography of *Crotalus viridis*

The authors examined approximately 1350 base pairs from the cytochrome b and NADH mitochondrial genes, to study the phylogeography of the Western Rattlesnake (*Crotalus viridis*). Specimens were sampled from throughout the range of this species, and represented all currently recognized subspecies. Parsimony and likelihood methods of phylogenetic inference were employed, and results of these analyses reveal two clades of populations. The first clade recognizes those populations east and south of the Rocky Mountains (*C. v. viridis* and *C. v. nuntius*), whereas the second clade includes those populations west of the Rocky Mountains. According to the authors, the conventionally recognized subsepecific diversity is not consistent with the phylogenetic pattern; therefore, a review of the systematic status of these subspecies is required. Results of this study also suggest that relatively small body size has evolved twice within this species, and that lethal toxins related to Mojave toxin arose within the complex including *C. v. concolor.*

Ontogenetic Plasticity in a Mexican Iguanid Lizard

An ontogenetic shift from insect consumption in juveniles to plant consumption in adults is relatively rare among herbivorous iguanids. This study of *Ctenosaura pectinata* documents an ontogenetic shift in the diet and anatomy of the digestive system in this species. Though *C. pectinata* was found to consume a variety of plant parts (foliage and flowers) in all age classes, non-adult lizards were found to utilize the broadest diversity of food items. Arthropods were found to covary seasonally with a decline in arthropod abundance for juvenile and immature lizards. The author rejects the hypothesis that the arthropod diet of juveniles is incidental to consumption of plant material because the size-adjusted morphology of the digestive system and its capacity was similar in all age classes, and because the arthropod density of all food plants surveyed did not have enough insect diversity to explain the proportions of plant/insects seen in juvenile lizards. The author supports the hypothesis that though juvenile *Ctenosaurus* can eat plants, they don't because insects offer a higher nutritional value. Finally, the author discusses the possibility that the broad diet of juveniles and immature lizards may offer benefits for these lizards by reducing searching costs, improving nutritional and energetic consideration, and increasing new food exposure of individuals in high-predation-risk periods of growth.

Phylogenetic Position of Caecilians

Zardoya and Meyer sequenced the complete mitochondrial genome (over 17,000 base pairs) of the caecilian *Typhlonectes natans*. These sequence data were combined with sequence data for other lissamphibians and tetrapods, and used to evaluate the phylogenetic position of caecilians and the origin of amphibians. Two data sets were analyzed (one examining protein coding genes, the other examining combined tRNA genes), and both supported the monophyly of a caecilian + frog clade. The results of this research could not resolve relationships among the coelacanth, lungfishes, and tetrapods, and the authors suggest that there is relatively strong support for a diapsid affinity of turtles. In a final phylogenetic analysis, the authors examined a mitochondrial rRNA data set for an expanded list of salamanders, frogs, and caecilians; results of this analysis support a frog + salamander clade. Rate heterogeneity in the rRNA data set is discussed.

Herpetofaunal Communities in Ghana

This article provides a summary of the herpetofaunal diversity surveyed at the Muni Lagoon during the primary rainy season. Of the 13 species of amphibians and 19 species of reptiles recorded at this site, none are endemic to Ghana, and only three species are first records for coastal habitats. Grassland thickets and freshwater ponds offered the most diverse herpetofaunal communities, and the authors suggest that conservation efforts in this region of Ghana should focus on protecting these two habitat types. Finally, the authors suggest that *Hyperolius, Python,* and *Varanus* may offer the greatest potential for undertaking long-term monitoring within these habitat types, as they are easily surveyed, and may be sensitive to a diversity of environmental stressors.

Directional Asymmetry of Two Families of Lizards

The author compares the ecology and evolution of directional asymmetry through ontogeny with that of its product, morphological directional asymmetry. Representatives of Lacertidae (*Acanthodactylus, Aldolfus, Eremias, Heliobolus, Ichnotropsis, Lacerta, Meroles, Mesalina, Ophisops, Pedioplanis, Podarcis* and *Takydromus*) and Agamidae (*Agama*)were included in this study. According to the author, variation in the morphological directional asymmetry reflects reversible adaptaions to the environment of these species, whereas variation in the developmental trajectory that produces the morphological directional asymmetry is independent from the immediate environment, but is determined by some evolutionary processes. Essentially, the environment was found to define the results of the processes of development of morphological developmental asymmetry, but not to affect the mechanisms of the process that produces this asymmetry.

Ecology of the Checkered Garter Snake

The authors studied the reproductive biology and ecology of *Thamnophis marcianus* in southeastern Arizona. Checkered garter snakes were found to be active at night and during the day; however, this activity was restricted to aquatic areas or adjacent habitats. The authors found this species to give birth to single clutches of young during late May or early June, significantly earlier than other populations of this species and nearly all other North American livebearing snakes. A discussion of the implications of early timing of birth, as well as geographic variation in reproduction is provided. In the case of *T. marcianus*, the authors regard phenotypic plasiticity in some traits of this species as the result of proximate environmental factors such as food availability and precipitation, and that offspring size has been canalized relative to food availability; therefore, this trait is relatively more amenable to geographic variation.

SEIGEL, R. A., N. B. FORD, AND L. A. MAHRT. 2000. Ecology of an aquatic snake (*Thamnophis marcianus*) in a desert environment: implications of early timing of birth and geographic variation in reproduction. American Midland Naturalist 143:453–462.

Distribution and Ecology of Leptodactyid Frogs in the British Virgin Islands

Between October 1993 and October 1997, the authors visited 17 islands, confirming all but three previous records of leptodactylid frogs, and finding 10 previously unreported populations. The four species occurring in the British Virgin Islands (BVI) are *Leptodactylus albilabris, Eleutherodactylus antillensis, E. schwartzi, and E. cochranae*. The biphasic life cycle and aquatic dependence of *Leptodactylus albilabris* contrasts with the direct development and terrestrial habitat use found in all of the species of *Eleutherodactylus*. Investigators used visual encounter surveys, auditory transect surveys and night driving methods to locate individual frogs. During one survey year (1996), recorded advertisement calls were played to induce calling. Data were recorded for both frog species (including SVL, weight, microhabitat use and perch height) and habitat variables (including presence/absence of bromeliads, amount of leaf litter, and vegetation height). Multiple regression analysis and one-way ANOVA were used to examine island factors versus number of species present, and body size of males versus years and islands, respectively. Area and elevation explained most of the variance in the number of species found on each island, with elevation as the far more important factor. While males did show a difference in size among islands, they did not among years. The number of calling males was weakly correlated with recorded habitat variables.

Description of Oogenesis and the Ovarian Histology of the American Alligator

This paper provides the first thorough description of the histological features of an adult ovary and associated oogenesis of a crocodilian. Phylogenetic relationships between crocodilians and birds suggests that there should be similarities in reproductive functional morphology between the two groups if these structures are conserved. Researchers surgically removed and studied the ovaries of 13 adult *Alligator mississipppiensis* from three lakes in Florida. Each ovary was histologically sectioned and placed into one of 10 folliculogenic stages (which are discussed individually in the article). The reproductive cycle was determined to begin in autumn with an increase in hormone concentration and subsequent vitellogenesis. Ovulation and gravidity occur during the following May/June. The authors found several features in common between *A. mississippiensis* and other reptiles, and other characteristics that were similar to those described for birds. Among those features uniting *A. mississippiensis* to other reptiles are follicular characteristics of the ovary in early follicular development. Bird/crocodilian shared characteristics include morphology of yolk platelets and the presence of an ovarian system of lacunae and

thick and smooth muscle bundles around follicles. The researchers observed several aspects of crocodilian folliculogenesis that lend support to the current theory of archosaurian evolution.

Molecular Phylogeny of Xenodontine Snakes

Xenodontinae is one of the largest subfamilies within Colubridae, and is comprised of nearly 90 genera, and over 500 species. Xenodontinae is believed to be restricted to the New World, the majority of species from Central and South America, as well as the West Indies. The authors have inferred the phylogeny of xenodontine snakes by examining portions of the 12S and 16S ribosomal RNA genes from 85 species. Results of this analysis support a monophyletic Xenodontinae and the basal position of a North American clade of xenodontines. The authors suggest that the inferred phylogeny and pattern of distribution supports an Asian–North American origin of the xenodontines. The West Indian xenodontines appear to form a monophyletic group that diverged from the South American xenodontines that originated by dispersal in the mid-Cenozoic. Finally, their results suggest that several morphological and ecological traits have evolved multiple times during the evolution of these snakes.

The Effects of Logging Roads on Amphibian Movement

The dominance of logging as a land use in areas like northern New England, makes requisite the understanding of impacts of logging practices on wildlife. This study looks at secondary forest road development and its role as a disturbance factor to amphibian species. Direct mortality from such roads is limited, as the frequency of vehicular traffic is generally light. However, the impact of these roads as a barrier to amphibian dispersal (natal, migratory and home range movement) is little understood. The authors used 6 pairs of drift fences with pitfall traps along each of two study sites: one wide (12 m) and one narrow (5 m) road, both in a logged area of Penobscott County, Maine. Fencing was placed near the road and within the forest as a control. The narrow and wide roads were each sampled for more than 12,000 trap nights, however sampling was completed during different years (1992 for the narrow road site, 1993 for the wide road site). Data was analyzed for eight amphibian species (four salamanders, four anurans). Recaptured animals and treefrogs were excluded from the data analysis. No significant difference in capture rates for anurans was found between forest and road traps at either site. However, salamander species were found preferentially in continuous forest habitat compared with traps near the larger road.

Different life history movement types (juvenile dispersal, adult migrations and home-range movement) were differently affected by the road barrier. Juvenile amphibians showed the highest crossing rate, while adult home-range movement was most restricted by the barrier. It was also demonstrated that forest surface activity of amphibians was positively correlated with the amount of rainfall during the trapping period. The effect was more profound in salamanders than anurans, and greater in control (forest) locations than traps nearest the roadways. In general, effects of secondary roads on amphibian species were found to be taxon and life history stage dependent.

Parental Investment and Resulting Potential Reproductive Rates of a Dart Frog

The investigators studied the gender-specific parental investment (time) of strawberry dart frogs (*Dendrobates pumilio*) and the resulting potential reproductive rates (PRR) of both males and females. Observations were recorded over a six-month period in Costa Rica, resulting in a description of the mating system of *D. pumilio* as a "sequential polygamy." This system is based on a sequential and simultaneous combination of polygyny and polyandry. Females are able to produce clutches continuously throughout the prolonged breeding season, and both sexes contribute to the parental care responsibilities. Females were observed to be more selective in their choice of mates than were males, and male mating success was found to be highly variable. Time required to rear one offspring was calculated to be 5 h total for males and 73.2 h total for females. Because females' parental investment is greater than that of males, females have a lower PRR, and are therefore the limiting gender as mates. Researchers also believe that because of the lower PRR of females, they are more selective in mate choice and therefore contribute to variable male mating success.

Mary L. Anderson (1918–1999)

ROGER CONANT
Department of Biology, University of New Mexico
Albuquerque, New Mexico 87131, USA

Few persons knew Mary Anderson, who was the baby turtles' best friend. She worked alone and even her family, who was well aware of her humane objectives, usually didn't know just what she was up to. When she needed help she called on me and other herpetologists for advice. She kept at it for 40 years and was instrumental in obtaining a ban on the sale in the U.S. of turtles with carapaces less than four inches in length.

To Mrs. Anderson the trade in baby turtles was a loathsome racket. The average vendor handled his living merchandise like cans of beans, with little or no thought for their welfare and comfort. Robert G. Hudson, an able agent for the Pennsylvania SPCA, reported finding a large aquarium in a pet store containing little turtles seven deep. Those on top were alive. All others were dead; those on the bottom were rotten from decay.

The vendors, to augment their income, raided turtle nests, dug up the eggs, and incubated them until they hatched.

Norman E. Hartweg, the University of Michigan's famous cheloniologist, often visited Reelfoot Lake in western Tennessee to study the huge populations of turtles of many species that the lake supported. On a trip during the early 1930s he found several large adult female red-eared turtles, *Trachemys scripta elegans*, that had been chopped open with a hatchet. The eggs had been removed and the mothers left to die. The eggs were doubtless added to others being incubated.

Mary Anderson was severely vexed by such atrocities, but she worried most about the more subtle problem that an enormous percentage of the baby turtles failed to survive when they reached their final owners. The vendors sold small parcels of dried ant pupae under the guise of being turtle food. How well I remember the hundreds of the little orphan reptiles donated to the Philadelphia Zoo over a period of many years. Virtually all were in an advanced state of malnutrition. Their eyes were swollen shut and their shells were soft from lack of calcium. We had to explain to the donors, often parents whose children were already weeping about giving up their pets, that there was nothing we could do except to put them painlessly out of their misery.

The sales of infant turtles were often the result of impulse buying. They were cute and colorful, and the vendors said they made wonderful pets for children. This sad scenario inspired Mrs. Anderson's first efforts on behalf of the turtles being sold as pets. She "rescued" many from horrible conditions in stores, took in others much like the ones we encountered in Philadelphia, and quickly realized that the care of these creatures was far more complex than suggested by those who sold them. At first she tried to address the problem of the totally useless commercial food, but soon realized that the only real way to end the cycle of abuse and cruelty was to prohibit the sale of turtles as pets altogether. The accomplishment of this basic humane goal was the driving force for all of the endeavors that followed.

Mary Anderson was an extremely shy person and scarcely anyone other than a few trusted friends and her family knew of her dedication to the hatchling turtles. She would not allow her name to be used. She preferred to work alone and to remain unknown. In the mid-1990s, as I was preparing the text for my memoirs ("A Field Guide to the Life and Times of Roger Conant," published by Selva and sponsored by the Toledo Zoo), I finally convinced her that the extraordinary work she had done should be recorded for posterity. She was not well and was suffering from severe osteoporosis. She finally gave me permission to use the following paragraphs from my book, which I am able to reproduce herewith through the kindness of William V. A. Dennler, executive director of the Toledo Zoological Gardens.

"In 1965 medical research documented the frequent occurrence of *Salmonella* bacteria in hatchling turtles sold as pets. During that year Mary L. Anderson, a dedicated and public-spirited person who was appalled by the health risk to children and the carnage among the little turtles, became deeply interested in the problem. She went to Washington and discovered that federal agencies knew little or nothing about the situation. After being advised to get in touch with the Centers for Disease Control, she learned that the CDC was trying unsuccessfully to solve the problem by using various chemicals in the turtle breeding ponds, and was conducting extensive research on the subject. Meantime, sales were increasing, reaching 15 million turtles annually and causing 280,000 cases of illness a year, mostly among children.

"In 1971 Mrs. Anderson successfully influenced her Congresswoman, Leonor Sullivan of Missouri, to introduce a bill calling for federal regulation of the turtle trade. Similar bills were offered by two other members of Congress, but they languished in committee. Senator Edward M. Kennedy then introduced a resolution calling for action by the Health, Education, and Welfare Department within 30 days. It was successful in requiring the issuance of a document certifying an absence of *Salmonella* bacteria before turtles could be shipped. In most cases, however, by the time the turtles arrived at pet stores the bacteria were present.

"The turtle vendors then came up with the asinine scheme of selling individual turtles in covered sterile bowls, but with the recommendation that the little reptiles be placed in water for a short time each day. Meantime, Mrs. Anderson kept the Animal Welfare Institute, the Consumers' Union, and the Humane Society of the United States aware of what was happening. The three organizations were finally successful in getting the Food and Drug Administration to issue a total ban on the sale of turtles with shells less than four inches long. The ban is still in effect as this is written.

"With their domestic market cut off, the vendors began selling red-eared baby turtles overseas. In 1984, when Kathryn [my wife] and I were in Hong Kong, I visited two snake shops in the futile

hope of finding a live member of the venomous *Agkistrodon* snake complex to photograph. In front of one shop was an aquarium with several baby red-ears swimming listlessly about in the water. Since then, the foreign market has grown to seven million turtles shipped in 1994 to 39 different countries."

I am lost in admiration for all Mary Anderson accomplished. She was a quiet, unassuming lady, but her constant prodding in the right places kept things moving for many years. Her extensive files have been given to Peter Pritchard and Anders Rhodin of the Chelonian Research Institute, who have agreed to make them available to interested researchers.

Notes on the Island Populations of the Western Rattlesnake, *Crotalus viridis*

KYLE G. ASHTON
Department of E. P. O. Biology, Campus Box 334
University of Colorado, Boulder, Colorado 80309, USA
e-mail: ashtonk@colorado.edu

Islands tend to be less complex than mainland environments and have been used to study patterns and mechanisms in ecology and evolution (e.g., Grant 1998; MacArthur and Wilson 1967). In addition, island populations of animals often show unique characteristics (e.g., rattleless rattlesnakes, Cliff 1954; Radcliffe and Maslin 1975). Yet, island populations of animals in general, and snakes in particular, are especially vulnerable to extinction (e.g., Dodd 1987, 1993). Accordingly, it is important to gather information on the status of island populations.

Klauber (1972) reported that the western rattlesnake, *Crotalus viridis*, occurred on five islands throughout its range, and to my knowledge this species has not been collected on any additional islands. The current status of the island populations of *C. viridis* is uncertain because there are no published records of specimens from four of the islands subsequent to those examined by Klauber (1972)—all of which were taken prior to 1956. Here I briefly review the historical records of *C. viridis* on each of the islands, the general history of each island, and present results of recent trips to three of the islands.

Klauber (1972) reported that *Crotalus viridis lutosus*, the Great Basin rattlesnake, occurred on Anaho Island, Pyramid Lake, Washoe Co., Nevada. Pyramid Lake is roughly 40 km long with an approximate surface area of 275 km^2 (Wheeler 1987; Woodbury 1966). Anaho Island is about 3 km^2 (Woodbury 1966) and approximately 0.8 km away from the mainland. In 1913 Anaho Island was declared a National Wildlife Refuge because in the summer it supports one of the largest breeding populations of white pelicans (Woodbury 1966). At one point sheep and pigs were probably introduced to the island (Woodbury 1966), but they have not been there for many years. There are no native terrestrial predators of *C. v. lutosus* on the island (Woodbury 1966), none have been introduced, and because there are no human inhabitants and human visitors are rare, the only predation is probably from birds.

The first *Crotalus viridis lutosus* specimen from Anaho Island of record was collected in July 1917 (CAS 43578). Forty-four additional museum specimens were collected between 1924 and 1961 (see material examined). Woodbury (1966) mentioned seeing several snakes on the island and suggested that there was a large population. From 16–19 August 1999, I visited Anaho Island and found eight individual *C. v. lutosus*, which included two reproductively active males and two pregnant females. Snakes on the island are substantially smaller than those on the nearby mainland (Ashton, unpubl. data), despite the relatively short distance separating them. It is possible that a large population of *C. v. lutosus* occurs on Anaho Island and the future prospects for this population are promising as long as the site continues to be protected and remains an island (the lake level dropped steadily between 1867 and 1982, but was never connected with the mainland; Wheeler 1987).

The northern Pacific rattlesnake, *Crotalus viridis oreganus*, has been captured on Rattlesnake Island in Clear Lake, Lake County, California. Clear Lake is about 30 km long and 13 km wide (Goldman and Wetzel 1963). Rattlesnake Island is the largest island in Clear Lake with a total area of about 0.15 km^2 (Mauldin 1968). At one point the island supported one of the largest Indian villages (Elem Indians) in Lake County (Mauldin 1968), but is currently privately owned. Mauldin (1968) reported that rattlesnakes were collected on the island and sold as part of an antibiotic to local mine workers, indicating that at one time there were many rattlesnakes on the island. Hogs were introduced to the island around 1960 and within a few years the rattlesnakes were apparently exterminated (Mauldin 1968). It is suggested that the hogs ate the rattlesnakes (Mauldin 1968), but their impact may have been more through decimating the snakes' prey and destroying habitat.

Only one museum specimen, a juvenile male, has been recorded from Rattlesnake Island (MVZ 34526). This specimen was collected on 21 June 1940. I planned on visiting the island in 1999 but was unable to gain access from the owner. The island is about 100 m from the mainland and it would be interesting to know if the island population is or was genetically differentiated from mainland individuals. Rattlesnakes are known to swim (Klauber 1972), so there may have been regular gene flow between the island and the mainland.

Another island population mentioned by Klauber (1972) is *Crotalus viridis oreganus* on Morro Rock, San Luis Obispo County, California. Morro Rock is one of the nine exposed San Luis Peaks, which originated 20–25 million years ago from volcanic activity (Dickerson 1990). Morro Rock rises 177 m and has an area of about 0.15 km^2 (Dickens 1983). From at least the Pleistocene until 1936, Morro Rock was an island (Dickerson 1990), separated from the mainland by 300 m of ocean water (Gerdes et al. 1974). In 1936 a causeway from the mainland was built, using stone from Morro Rock, to facilitate quarrying that had been going on since 1891 (Dickerson 1990). In 1963, quarrying ceased and in 1973 Morro Rock was declared an ecological preserve, primarily to minimize impact on nesting peregrine falcons (Dickerson 1990).

There are four museum specimens documenting the presence of *Crotalus viridis oreganus* on Morro Rock. The first was collected

in 1930 (SDNHM 2696), which was prior to the connection of Morro Rock to the mainland. I have been unable to find any information on whether there was an established rattlesnake population on Morro Rock before the causeway was built—the first published study of the fauna of Morro Rock was in 1957 (Munro 1957). The last rattlesnake observed on Morro Rock was collected in June of 1975 (CPSU H-3523). I visited Morro Rock on 8 August 1999 and again on 12 August 1999, but found no rattlesnakes on either day. I saw many *Sceloporus occidentalis* (25 different individuals in a single hour) and two *Elgaria multicarinata*. The snakes on Morro Rock may have been dwarfed, based on Klauber's (1972) report of a pregnant female that was only 467 mm SVL, and smaller *C. viridis* typically feed on lizards (Mackessy 1988; Ashton, unpubl. data). Hence, there is currently sufficient prey for *C. viridis* on Morro Rock. Additionally, small mammals were captured at the base and top of Morro Rock in 1980–1981 (Dickens 1983).

Feral cats have been a problem on Morro Rock, especially during the 1970s and 1980s (A. Roest, pers. comm.). In 1981, 12 individual feral cats lived on Morro Rock (Dickens 1983); by 1986 this number had increased to 21 (S. J. Marek, unpubl. data). The California State Parks and Recreation Department has been trapping and removing feral cats in the 1990s; there are currently no feral cats on Morro Rock (V. Cicero, pers. comm.). Feral cats may have affected rattlesnakes on Morro Rock by reducing their prey population and possibly killing rattlesnakes. It is possible that the lizard population on Morro Rock decreased during 1970–1990, because of feral cats, and the abundance of lizards during my visit was a recent phenomenon that has occurred as a result of the extermination of feral cats. Unfortunately, Dickens (1983) did not present any measure of abundance of lizards that could be compared with my recent observations.

Dickens (1983) spent one year surveying vertebrates on Morro Rock and failed to find any rattlesnakes. Falconers have been visiting the Rock for many years to study the nesting peregrine falcons and have never seen a rattlesnake (V. Cicero, pers. comm.). These observations, along with my recent visit, suggest that *Crotalus viridis oreganus* no longer occurs on Morro Rock.

The southern Pacific rattlesnake, *Crotalus viridis helleri*, occurs on one Channel Island— Santa Catalina Island, Los Angeles County, California. Santa Catalina Island is a continental island that is located 32 km from the mainland, with an area of 194 km^2 (Schoenherr 1992). This island has a long history of private ownership. In 1972, the Wrigley family created the Santa Catalina Island Conservancy and in 1975 they donated 86% of the island to the Santa Catalina Island Conservancy (Mallan 1992). The island also has a long history of impact from introduced species. In 1827, goats were introduced to the island and still remain (Schoenherr 1992). Pigs, deer, cattle, horses, and bison have also been introduced, although today only pigs, goats and bison remain in large numbers (Mallan 1992; Schoenherr 1992). The bison population is maintained at 200–400 individuals and the Santa Catalina Island Conservancy has been working, successfully, for many years to eradicate goats and pigs from the island. Nonetheless, these animals have been numerous and have caused substantial damage across the entire island (Schoenherr 1992). Unfortunately, there are no data on abundance or distribution of rattlesnakes prior to the introduction of these species so it is impossible to directly assess the impact of these introductions on rattlesnakes. However, several longtime human residents of the island suggest that rattlesnakes are less common today, especially since the introduction of pigs.

Crotalus viridis helleri have been collected on Santa Catalina Island since 1910. The most recent museum specimen was captured in 1967 (MVZ 81740). During the first week of August 1999, I visited the island and found five individuals at four separate localities. Additionally, many locals reported seeing snakes during the duration of my trip. Based on these reports, the specimens I captured, and museum specimens, it appears that *C. v. helleri* is relatively common and widely distributed on the island. The future of *C. v. helleri* on Santa Catalina Island is promising because most of the island is protected, which minimizes direct human destruction, and introduced species are being eradicated.

Probably the best known island population is on South Coronado Island. This island is the largest of the four Coronado islands and is located just south of the U.S.–Mexico border, 12 km west of mainland Baja California Norte, Mexico (Ellsberg 1970; Zweifel 1952). The island is about 3 km^2 in total area (Zweifel 1952), yet rattlesnakes on the island may be primarily limited to about 1.5 km^2 of habitat because of the steep sides of the island (Rubio 1998). Rattlesnakes have been captured on South Coronado Island for many years; museum specimens range from 1898 to 1976 (no specimens have been collected on any of the other Coronado Islands). They appear to be either abundant or very easy to find. For example, Zweifel (1952) recounted a brief trip during which he captured eight snakes. I planned on visiting this island in the summer of 1999, but was unable to obtain all the necessary permits in time.

There have been relatively few human occupants of the Coronado Islands, at least in part because of a lack of fresh water. From 1870–1880 the islands were used for fishing, quarried for rock, and mined for copper (Ellsberg 1970). In the 1930's a resort hotel was built on South Coronado Island, but it was a failure (Ellsberg 1970). Since that time the Mexican military has maintained a base on the island (Ellsberg 1970). Even though there have been few inhabitants of the islands, direct and indirect effects of humans have still resulted in local extinctions (Oberbauer 1978). At one time goats were introduced to the island, but were gone by the 1950's (Ellsberg 1970). However, on a recent trip to South Coronado Island, Rubio (1998) reported that goats and mules had been reintroduced. The island is mainly covered by low grasses; thus, it may not take long before the snakes have virtually no vegetative cover (Rubio 1998). This could lead to increased avian predation on lizards, the primary prey of the snakes (Klauber 1972), and on the snakes themselves. It is essential that monitoring begin soon to evaluate the impact of goats and mules on the abundance and distribution of rattlesnakes on the island.

This population was described as a separate subspecies, *Crotalus viridis caliginis*, by Klauber (1949), but this designation has not always been followed (e.g., Stebbins 1985). The main difference between *C. viridis* on the island and those on the adjacent mainland (ssp. *helleri*) is body size (snakes on the island are much smaller than those on the adjacent mainland). Genetic studies are underway to assess the relationships of this island population to those from the nearby mainland (Ashton, unpubl. data).

It is striking that *Crotalus viridis* is dwarfed on all four of the islands for which data are available (Klauber 1972; Ashton, unpubl. data). Case (1978) suggested that in general snakes are dwarfed on islands, but he did not present data on the strength of this trend. Certainly there are well known exceptions (e.g., Schwaner 1985; Schwaner and Sarre 1988). What determines body size of snakes on islands? Prey size seems to be the best correlate; larger prey means larger snakes (Forsman 1991; Schwaner 1985; Schwaner and Sarre 1988). On the islands with the smallest body sizes, Anaho Island and South Coronado Island, the only available mammalian prey is a single species of *Peromyscus* (Oberbauer 1978; Woodbury 1966). The snakes on Santa Catalina Island are dwarfed compared to the mainland, but are larger than on the other islands (Ashton, unpubl. data). The largest potential mammalian prey species on Santa Catalina Island is a ground squirrel (*Spermophilus beecheyi*; Mallan 1992). Thus, body sizes of *C. viridis* on islands appear to be consistent with the idea that snake size is positively correlated with prey size. Shine (1987) points out that island size differences may be a direct result of food availability as opposed to responses to selection. The genetic basis of body size variation among island and mainland populations of *C. viridis* deserves study.

In summary, there are three islands that currently support populations of *Crotalus viridis*. One island that no longer appears to have a population of rattlesnakes, but did so historically, is Rattlesnake Island in Clear Lake. Morro Rock used to be an island, but it is unknown whether a distinct population ever occurred there prior to its connection to the mainland about 60 years ago (only one individual of record was captured when Morro Rock was an island). It now appears that there are few, if any, rattlesnakes on Morro Rock; none have been collected for about 20 years. The population on Anaho Island appears to have been the least impacted by humans, and probably contains a large population of snakes. Introduced animals certainly have affected *C. viridis* on Santa Catalina Island, but the snakes seem to be fairly common and may increase in abundance as pigs and goats are eradicated. The future of the population on South Coronado Island is uncertain. *Crotalus viridis* is dwarfed on four of these islands (no data exist for one of the islands). Studies on the distribution, natural history, life history, and genetic relationships of *C. viridis* on Anaho Island and Santa Catalina Island are currently underway (Ashton, unpubl. data).

Acknowledgments.—For permission to examine museum specimens under their care I thank J. Vindum (CAS), A. Roest (CPSU), J. Simmons (KU), J. Seigel (LACM), D. B. Wake and H. W. Greene (MVZ), S. Shelton and B. Hollingsworth (SDNHM), R. E. Espinoza (UNR), K. deQueiroz (USNM), and J. Campbell (UTA). I thank the SDNHM for access to the Klauber Herpetological Library and T. Reeder for lodging during my visit to San Diego. For permits, information, access, and lodging I thank: F. Starkey, P. Schuyler, J. Jensen, J. Takara, S. Story and the Santa Catalina Island Conservancy; Dept. of Fish and Game, California; V. Cicero and the California State Parks and Recreation; N. Scott and the Piedras Blancas U.S.G.S. biological research station; B. Henry, D. Withers and the U.S.F.W.S. Stillwater National Refuge; Bev and Brian and the Pyramid Lake Indian Tribe. For field assistance I thank J. Jensen, D. Bratt, N. Scott, and especially J. Richmond and D. Carpenter. I thank H. W. Greene and A. Roest for discussion of island populations; J. Lemos-Espinal for help with permits to access South Coronado Island. For funding I thank the Explorers Club; the Department of E.P.O. Biology, University of Colorado; and the Walker Van Riper Fund, University of Colorado Museum. I thank D. Chiszar, A. de Queiroz, J. Reed, and H. M. Smith for comments on this manuscript.

Little is known about the reproduction and larval development of the large (up to 16.7 cm SVL, Heyer 1979; Kaiser 1994) terrestrial frog, *Leptodactylus fallax*, because of its cryptic nesting behavior and currently restricted distribution only on parts of two Caribbean islands, Dominica and Montserrat. Breeding of *L. fallax* is thought to be initiated by rainfall, with male calling concentrated from mid-February to September in Dominica. As prolonged breeders (Stebbins and Cohen 1995; Wells 1977), females breed asynchronously, and males have stationary calling sites and antiphonal calling. Eggs are deposited in foam nests in cavities under rocks, logs, or in stumps (Brooks 1968) where larvae complete their development (Lescure 1979). Lescure and Letellier (1983) reported that the larvae live and grow in the foam nest only on their vitelline reserves until metamorphosis. The nests are extremely difficult to locate due to asynchrony of breeding and to concealed nest cavity entrances. Brooks (1968) and Lescure (1979) indicate that the female remains with the eggs and larvae in the cavity until the froglets emerge.

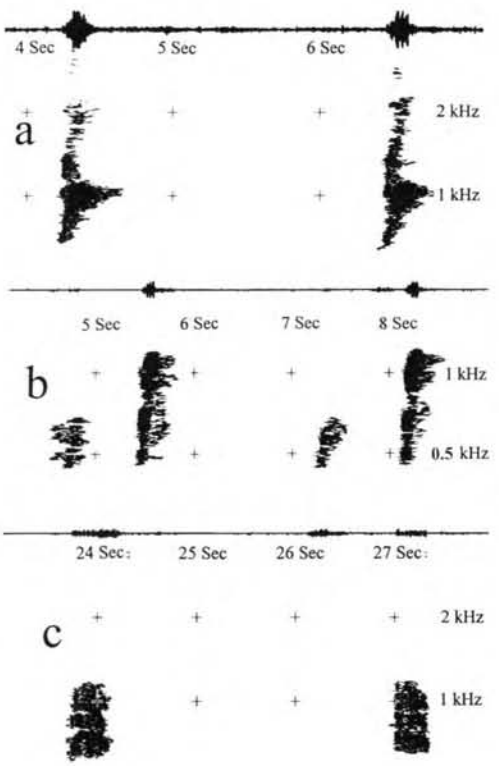

FIG. 1. Calls of *Leptodactylus fallax*. a) male advertisement call, with harmonics, oscillograph (top), sonograph (bottom); b) duo of type 1 female call (first) and male call (second); c) type 2 female call.

Our research had three aspects: 1) study of a captive, caged pair of frogs, 2) observations of adult calling in nature, and 3) study of larval development in a nest cavity. Prior to our study, no one had followed the development of *L fallax* larvae in a nest in the field.

Our study was carried out from February to June, 1996, at the Springfield Estate at 290–390 m elev., 5.5 km NNE of the Dominica (W.I.) capital, Roseau (15°20'N, 61°23'W). The property occupies mountainous terrain largely covered by abandoned tree crops and gardens in various stages of succession to forest, and second growth moist evergreen forest with a few deciduous species. All observations were centered around and within 500 m of a small cluster of buildings.

An adult male and female *L. fallax* were placed in a wire mesh cage (1.4 x 2 m) at Springfield on 11 February. These were provisioned with natural objects for shelter, and daily with water and small invertebrates as food. We observed the frogs 1–2 h each day just before dawn and just after dusk until 29 April. Over four months, behavior and calls of the captive frogs were noted and tape recorded.

From the cage we also could readily hear five wild *L. fallax* males, spaced ~20–100 m apart. Site specificity of these different individuals was confirmed by reconnaissance. Each wild male maintained the same calling site night after night throughout the

study period. The calls of both males and females were digitized and analyzed using Spectrogram version 4.2.2a (Horne 1994) software. Considerable effort was made to locate nests, including advertisement of a cash award for anyone who could point one out to the researchers. None was reported.

Starting 2 March, we directed our attention to a male that called from a cavity under a patio at Springfield. Mating and foam nest production took place in the cavity six weeks later, and subsequently we followed the development of the larvae in the nest. We observed the nest with a small angled mirror on the end of a 0.7 m rod. A beam from a fiber-optics light enabled us to clearly observe the interior of the cavity including the foam nest. We made almost daily observations of the larvae until 15 May, followed by 11 observations, irregularly spaced between 16 May and 17 June. Video footage of the larvae in the nest and froglets in the cavity out of the nest was obtained on several occasions in late May and early June. On 8 May, we collected two larvae and a small amount of foam for microscopic study, and subsequently sent these to W. R. Heyer for deposit in the National Museum of Natural History, Smithsonian Institution collection (accession USNM 510211).

Starting in late February, males began advertisement calling at night (Fig. 1a). At dawn, some males and females gave a brief bout of low intensity calls. On rare occasions males called briefly during the day. Each call increased in frequency from beginning to end, and had up to three high frequency harmonics (Fig. 1a). Average wild male call duration at night was 0.248 sec (N = 166 calls, CV = 17.6%), dominant frequency 1170 Hz (CV = 15.1%), and inter-call interval 1.887 sec (CV = 104.8%). However, these results incorporate at least three sources of variance: different individuals (3 identified males; 7 unknown males), different bouts of the same individual, and different calls within a bout. No differences were found between call duration and interval of the same male, but the two males with multiple bout records differed in frequency between bouts (t-tests p = 0.003 and 0.0004, respectively). These two males were marginally different from each other in call duration (t-test, 2 bouts per male, p = 0.028), suggesting that duration may be important for recognition of individuals. Further study of reproductive behavior of this species should include a more thorough analysis of call components as they relate to mate selection by females.

The captive female frog calls were always much quieter and different in quality (Figs. 1b and 1c) from male advertisement calls. Concealed wild frogs were identified as female on the basis of these distinctive calls. Females sometimes initiated calls and sometimes responded to male calls. Two types of calls were recorded from the captive female. One type (Fig. 1b; N = 12 calls) increases in frequency from beginning to end, and has an average duration of 0.127 sec (CV 15.3%), dominant frequency 538 Hz (CV 16.2%), and inter-call interval 1.828 sec (CV 11.3%). The other type (Fig. 1c; N = 14 calls) maintained a constant frequency range with no dominant frequency, but with three bands of spectral power. The average duration was 0.322 sec (CV 11.3%), with recorded frequency of 370 to 1300 Hz, and inter-call interval 3.049 sec (CV 34.3%).

Advertisement calls of different males did not overlap. When one male called loudly all night, others within our hearing range remained quiet. All-night callers took turns on different nights. On some nights, shorter-term callers made a duet, or a trio, with each male's call alternating (antiphonally) with the other(s). The duration of trios was shorter than that of duets. Males typically

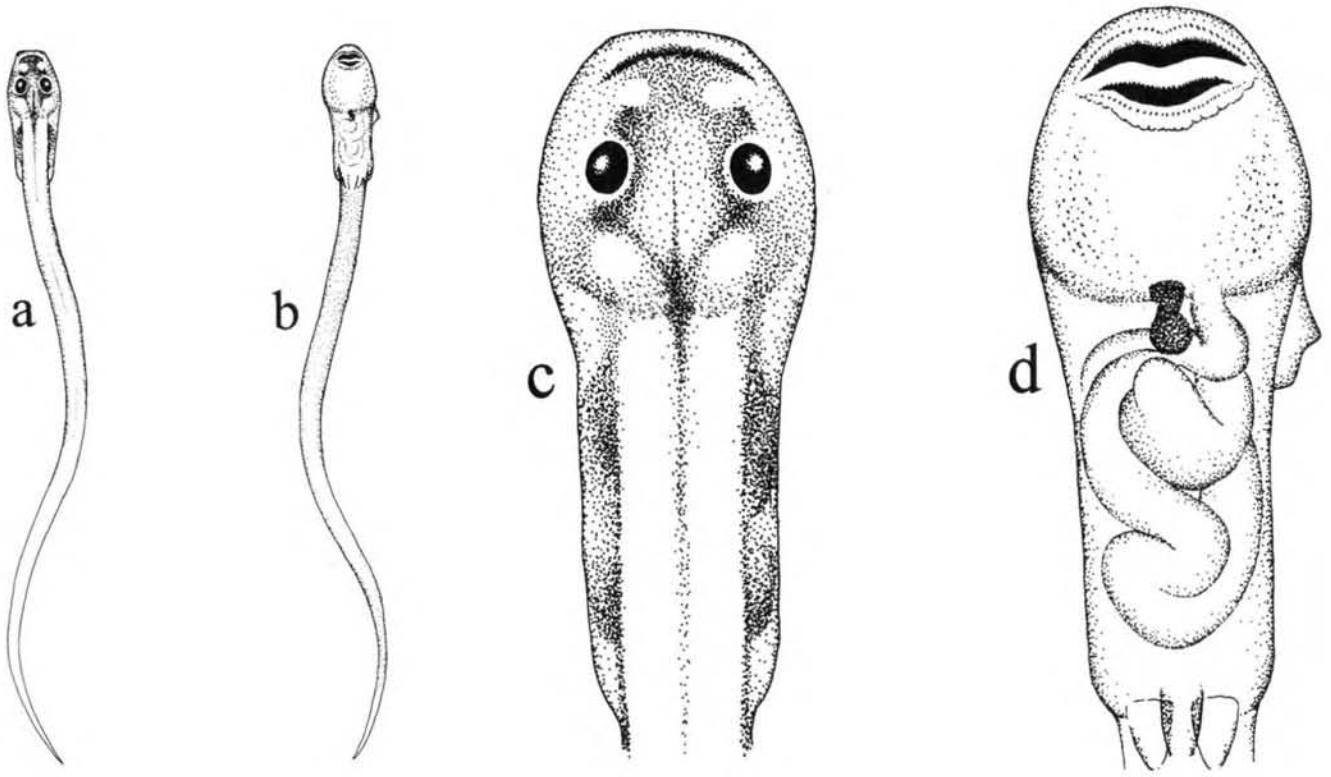

FIG. 2. *Leptodactylus fallax* larva, 24 days old. Total length 6.0 cm, tail 4.9 cm, body 1.1 cm, body max. width 0.45 cm. a) whole larva, dorsal; b) whole larva, ventral; c) body, dorsal; d) body, ventral (denticle rows sketched—not an accurate count).

called very little during dry series of nights.

Our observations confirm that mating can occur as early as mid-April, and is preceded by mostly dry weeks, as reported by Lescure (1979). In 1996, a dry period ran from mid-March to mid-April. It started to rain on 13 April. At 2300 h on the rainy 14th of April, a male *L. fallax* began rapid-fire calling from his cavity. A frog sped away when we moved some rocks to facilitate observation of the cavity entrance. A few minutes later that frog, undoubtedly the female, returned and entered the cavity where the male frog was calling at ~120 times/min. The female joined his calls every fourth note in a synchronous manner. After a few minutes, all was quiet until 0130 h when the male resumed rapid-fire calling for approximately 15 min.

The first time (22 April) that we looked into the cavity, we saw an adult frog (sex not determined) in front of a foam nest. On the nights of 16 April and 15 May, a male called from in or adjacent to the cavity, but between these dates the closest male calls (the same male?) were a few meters away. After 22 April, we saw no adult frogs in the cavity, despite reports that the female remains with the larvae during development. However, she could have been out of view in an obscure chamber of the cavity.

The cavity entrance was at the bottom of the cement foundation wall of a raised patio, in a position that was difficult to access, not frequented by humans, and obscured by thick weedy vegetation and a jumble of rocks. The entrance, a gap in the base of the wall, was ~20 cm wide and highest (~10 cm) in the middle. The interior (main chamber) was 20–25 cm wide, 10–15 cm high, and ~50 cm deep, with a near-horizontal floor of hard, moist soil. The foam nest occupied a shallow depression in the floor near the inner end of the main chamber. The nest was ovoid, 14 x 11 cm, and 2–4 cm deep in the middle, but these dimensions diminished between times of foam replenishment. The temperature in the cavity remained at 23°C.

On 25 April, we made our first observations of larvae in the foam. It was difficult to determine the size of the brown and translucent larvae, and difficult to count them because they thrashed about in a wet mass, but on 28 April and subsequent dates we were able to determine that 15–20 were present. The larvae were totally submerged during some observation periods, when we could see only the motionless or churning foam; at other times they were active at the surface where we often saw many opening and closing mouths rising out of the foam. As the larvae grew larger, they rose more frequently above the foam surface. In a typical activity period, 5–10 sec in duration, most or all of the larvae moved simultaneously and energetically, their long tails in a writhing tangle. Of the three larvae spooned up on 8 May, one was 6.0 cm and the other two 3.0 cm long (two were preserved; one small one returned to the nest). Two- to three-factor differences in linear dimensions of larvae persisted throughout the period of observation.

No yolk sac was present on the large and small 24-day old larvae collected on 8 May (Fig. 2), nor were yolk sacs observed later on larvae in the foam. Therefore, the claim of Lescure and Letellier (1983) that *L. fallax* larvae are nourished only by their vitelline reserves until metamorphosis is not supported by our observations. By late May, hind legs were present on some larvae, and on 7 June, six froglets were observed out of the nest but inside the cavity. Their lubricated bodies were ~3 cm long, and only a vestige (rounded stump) of the tail remained. Froglets jumped back into the nest, suggesting that "fledging" is a gradual process. On 7 and 10 June, only a small number of larvae remained in the foam. By 12 June, only two "mature" larvae (not quite froglets) were in the foam, and we saw one froglet in the cavity outside the foam. On 17 June, no foam or larvae remained, nor did we see froglets in the cavity. On 28 June we saw one froglet in the cavity, indicating continued use of the cavity after the nesting period.

The collected larvae had light brown bodies, and translucent, worm-like tails (Fig. 2). Major dimensions of the 6.0 cm specimen were: body length 1.1 cm, max. body width 0.45 cm, tail 4.9 cm (Fig. 2). The smaller larvae (3.0 cm) were less pigmented than the large one, but superficially similar. The jaws had serrated horny beaks and one row of anterior labial denticles. The posterior labium had a discontinuous row of denticles (Fig. 2c and d). Larvae in the nest in late May and early June continued to vary in pigmentation.

The foam from the nest contained numerous round cells, each ~30 µm, too small to be *L. fallax* ova (as reported for other nests by Lescure and Letellier 1983). On 5 May, the foam contained red streaks and tissue debris. On 8 May, dividing "embryonic" cells and at least two sets of black spine-like structures resembling *L. fallax* beak serrations were in the foam. On 13 May, ciliated protozoa and a nematode were observed in a drop of foam. On 10 May, fresh crab legs were present inside the entrance of the cavity.

The foam was periodically replenished, making the nest higher and whiter. Recently replenished foam was observed on 2, 9, 12, and 23 May, and on 7 June. Between replenishments the foam diminished, on occasion barely covering the developing larvae in a small area of the soil depression.

The type of nest cavity used by *L. fallax* is quite variable, apparently depending on availability. Our captive frogs, caged on hard grass-covered soil, did not attempt to burrow or dig out of the cage. This species does not appear to have the anatomy to do so. However, a captive individual dug a nest cavity in peat at Lescure and Letellier's (1983) laboratory. The nest cavity we studied and another observed by one of us (A.J.) in Dominica were both associated with human buildings. Other reported *L. fallax* nest cavities in Dominica have been in agricultural (e.g., base of a banana tree) or natural vegetated environments (Lescure 1979). On Dominica, numerous burrows are dug by land crabs and rats. The cavity we studied had human debris in it, including a toothpaste tube, suggesting that it may have been dug and/or occupied by rats, which are numerous in the vicinity.

An unresolved question is: do the larvae feed, and if so, how? Lescure (1979) and Lescure and Letellier (1983) maintained that *L. fallax* larvae do not feed, but live off their yolk. However, we found no yolk in larvae three weeks old, with six more weeks of growth ahead. Our observations lead to three hypotheses on larval nutrition; they need not be exclusive: 1) the female replenishes the nest with nutritious secretions from her body, perhaps containing oocytes or other cells; 2) one or both parents provision the young with prey; and 3) larval cannibalism occurs, most likely the large larvae consuming the small ones.

The repeated replenishment of foam is consistent with the first hypothesis. In addition to maintenance of a quasi-aquatic environment for the larvae, the replenishment could renew the food supply. The secretions for the foam may be composed of muco-

polysaccharides and mucoproteins, as are the gelatinous egg capsules (Stebbins and Cohen 1995), although we have found no published analyses of foam chemistry. *Leptodactylus pentadactylus* and *L. labyrinthicus* larvae eat the foam before moving to a nearby water body (Lescure and Letellier 1983). The small cells we observed in the foam may have come from an attendant parent. Several cases of females returning to oviposition sites to lay unfertilized eggs as food for their offspring have been reported for other species (e.g., Lannoo et al. 1987). Lescure and Letellier (1983) noted about 150 eggs together with the *L. fallax* larvae in a foam nest at their laboratory. The microinvertebrates we observed suggest that the foam supports a culture of organisms that also could serve as nutrition for the larvae.

Females must accumulate sufficient fat reserves before seeking males for mating. If females must also repeatedly replenish the foam and, possibly, add unfertilized eggs to it and/or provision the larvae with prey, it is necessary for them to draw on reserves to fulfill these functions. The mother is said to refuse food during the period when the larvae are developing, at least in captivity (Lescure and Letellier 1983; R. Johnson, pers. comm.). We question whether it would be possible for wild *L. fallax* females to nourish the larvae in any of the above modes without feeding during the nesting period of two months.

The second hypothesis is supported by the presence of prey remains, namely the fresh crab legs inside the cavity entrance. The red streaks and multiple flesh bits in the foam could have come from prey, or could be the remains of larvae—supporting the third (cannibalism) hypothesis. The black beak-serrations in the foam also support the third hypothesis. However, small as well as large larvae survived throughout larval development, and the total number of larvae did not noticeably diminish during the two months of observation.

Leptodactylus fallax nests are extremely difficult to find; nevertheless, the lack of observation of more than one nest is an obvious weakness in our study. It may be possible to radio-tag potential parents and follow them to find more nests. One also might try setting up artificial nesting cavities with removable lids in likely nest areas and monitor them periodically. If a nest were found, one could install a recording device such as an infrared camera to record parental and larval behavior. In addition, it may be possible to implant small radio transmitters under the skin of adult frogs to track their movements relative to the nest cavity and, in combination with recording devices in nest cavities, learn whether and how they provision the larvae.

Acknowledgments.—We are grateful to Springfield Centre for Environmental Protection, Research and Education (SCEPTRE), especially Mona George-Dill and David Lang, and to the Forestry and Wildlife Division, Ministry of Agriculture of Dominica. We also thank G. Auguiste, E. Harris, R. Heyer, L. Honychurch, R. Johnson, and A. Ohler. Mark McCollough produced the final drawings of the crapaud larvae.

A Novel Technique for Gathering Turtle Nesting and Emergence Phenology Data

Logistical problems often serve as roadblocks, preventing researchers from answering potentially important questions about a species' biology. However, these roadblocks often crumble under the mighty hand of technology. For example, discovering how many fathers sire a brood by direct observation was virtually impossible for most animal species until the development of DNA microsatellite techniques made achievable that seemingly unreachable goal. Similarly, nesting and emergence phenology has been little-studied in turtles because of the logistical problems presented. Until recently, obtaining data on hatchling turtle emergence has required up to hundreds of person-hours monitoring several nests continuously (e.g., Gyuris 1993) during the period in which turtles would be expected to emerge. Such logistical challenges are often not met, particularly when the outcome is not of general interest or relevance to management. For example, the question "What time of night/day do turtles nest?" is descriptive and may seem inherently trivial when viewed from an evolutionary or management perspective. However, when placed in the context of whether turtles can predict and manipulate offspring sex, for example, the

FIG. 1. Photograph, taken by Trailmaster® camera setup, showing tagged gravid *Carettochelys insculpta* emerging to search for a nest site.

question becomes more important.

During a three-year study of ecology and sex determination of pig-nosed turtles (*Carettochelys insculpta*) in northern Australia, we discovered an efficient remote data-collection technique for 1) determining nesting times of mothers, 2) determining emergence times of hatchlings, and 3) linking mothers to nests. Nesting times help us answer the question of whether or not mothers could control offspring sex, and linking mothers to nests can be used to test this idea. Emergence data can be used to address the idea that synchronous emergence is adaptive in turtles.

The technique is simply a modified use of the TRAILMASTER® infra-red remote trail monitoring system. Originally designed for tracking mammals (e.g., Tarpy 1997; Tuberville and Burke 1994), the TRAILMASTER® (TM1500) can be attached to a 35 mm automatic camera (TM35-1) which photographs animals when the infra-red beam is broken. A transmitter (12 cm L x 8.5 cm W x 5 cm D) sends the beam to a receiver (19 cm L x 8.5 cm W x 5.5 cm D), which has a digital display and memory. The receiver records the date and time of each event (can store up to 1000 events), and whether a photograph was taken. Both the receiver and transmitter run on 'C' cell batteries. Costs are US $260 for the TM1500 and US $290 for the automatic 35 mm camera kit (Olympus® TM 35-1). The camera kit includes an interface cable and mounting apparatus. Although the systems can be used without a camera, without confirmatory photographs the researcher cannot be sure that the animal crossing the beam was the target species.

To record nesting, we placed the transmitter box on one end of a nesting beach and the receiver box on the other, in a line near and parallel to the water's edge (boxes were less than one meter above water). The boxes can be placed as far as 30 m apart. The camera, attached by a cable to the receiver box, comes with a mounting apparatus, which we attached to a metal post driven into the sand in shallow water, a few meters from the beach. Larger beaches can be accommodated by moving the camera setup farther from the beach. However, because we were also interested in identifying mothers, cameras were placed close enough to the beach to ensure that identification (cattle ear) tags could be read in photographs (Fig. 1). To record emergence, the boxes were placed 0.3 m apart, just to the river side of previously discovered nests, near the time they were expected to hatch (Fig. 2). The camera setup was similar to that used to record nesting, but placed directly above the nest. To link mothers to nests we surveyed beaches daily for nests. When a fresh nest was found we recorded the date and time stored by the receiver, and compared it to the date and time superimposed on the developed photographs. Matching photographs were then examined for readable identification tags (cattle ear tags mounted on the rear carapacial edge) for individual identification.

The technique was highly successful at efficiently providing data to answer the following questions for *C. insculpta*: (1) When do turtles nest, by day or at night? What time? Do sand temperatures during nesting correlate with nest temperatures during the sex-determining period of offspring? When do hatchlings emerge, by day or at night? Exactly when? Do they emerge singly, in groups, or all at once? Are they more likely to emerge during/after rainfall? For example, *C. insculpta* hatchlings emerged around midnight (mean = 2348 h ± 147.4 min SD; N = 67; range = 1756–0456 h) at an average nest temperature of 33.0 ± 2.2°C (N = 64, range = 28.8–35.0), and hatchlings emerged at a greater frequency on nights after rainfall (0.92) than expected (0.60) on nights when no rainfall occurred. Our data are being published elsewhere (Doody et al., in prep.).

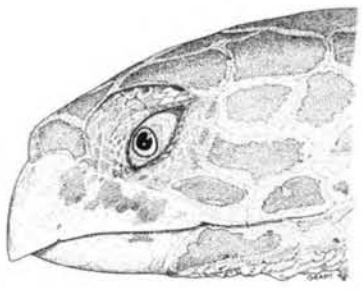
We used 15 infra-red setups to obtain these data, but the staggering of nesting and emergence in most turtles means that setups

FIG. 2. Hatchling *Carettochelys insculpta* emerging from the nest. Emanating from the nest are datalogger probes.

could be employed on more than one nest in a season, and so fewer setups could be used to collect an adequate amount of data. Maintenance included changing batteries periodically (ca. every 2–3 weeks) in both the boxes and in the camera ('AA' cells), changing film, and keeping the beam free of debris and new vegetation. Although the setup is weatherproof, we placed cardboard over the boxes to protect them from heat due to intense solar irradiation. Care should be taken when systems are used in flood-prone areas.

Limitations to the technique are mainly those associated with its use to link mothers to nests. For example, if the nesting beach or area is too wide along the water's edge (i.e., > 20 m), then the field of view of the camera may not cover the entire area where turtles will emerge from the water (moving the camera too far back will result in photographs with images too small for individual identification). The technique may not be useful for species in which discrete nesting areas cannot be identified. We also noted that birds were fond of perching atop the camera systems, often resulting in cameras being off-center. Care must be taken to ensure that batteries are viable and that a sufficient number of pictures remain. These problems can be eliminated by frequent monitoring of the system.

It is our hope that this system will be adopted by researchers to help fill in the gaps of our knowledge of nesting and emergence phenology in turtles. Indeed, the system can be used for other questions associated with nests, such as predator identification (R. Shine, pers. comm.). Behavioral studies with robust funding may wish to use video cameras in place of still cameras. This can be accomplished with the TRAILMASTER® TM700v kit (US $595), which can be attached to any video camera. Detailed information can be obtained from the TRAILMASTER® web site (http://www.camera-trap.com).



Acknowledgments.—The research utilizing this technique was supported by an Australian Research Council Large Grant awarded to Arthur Georges. The manuscript was improved by W. Branson and an anonymous reviewer.

Color of Pitfall Affects Trapping Success for Anurans and Shrews

ERIC CRAWFORD*

Monitoring amphibian populations often is done by call surveys, use of cover boards, or trapping programs (Heyer et al. 1994). A common type of trap for terrestrial surveys is a pitfall, which usually is made from metal cans or large plastic containers, such as those used to package ice cream or cottage cheese for restaurants (Corn 1994; Vogt and Hine 1982; Yunger et al. 1992). Although metal cans are inexpensive, there are drawbacks to their use. Cans only come in specific sizes, and changing the length (depth) of the pitfall requires cutting the metal or joining multiple cans together, often with tape (Corn 1994; Vogt and Hine 1982). In addition, cans and tape deteriorate, especially when placed in moist soils, and consequently, traps must be replaced during multiyear projects.

Although plastic containers will not deteriorate, they also may need to be joined to achieve adequate depth, and another potential drawback is that they typically are white in color (e.g., Yunger et al. 1992). Although color of trap influences capture success for insects and small mammals (Leong and Thorp 1999; Suplinskas 1987), this phenomenon has not been examined in amphibians. In this study, we introduce polyvinylchloride (PVC) sewer pipe as a long-lasting material for making pitfalls, and we also investigate the effect of color of trap (black or white) on capture success.

Pitfalls were made from smooth-walled PVC pipe (Schedule 40, Bristolpipe Corporation, Bristol, Indiana, USA) that is readily available at plumbing supply stores. Such pipe is either black or white on the inside and made in a variety of sizes (diameters). We used pipe that is 15 cm wide (cost: US $12 per 3-m length), because it approximates the size of metal cans (#10) that often are used to make pitfalls (Corn 1994). Using a hand saw, we cut each pipe into seven pieces that were about 44 cm long.

In the field, pitfalls and drift fences were placed in Y-shaped arrays (Corn 1994). In the center of each array was a single large pitfall (a 20-liter bucket). Extending from the central pitfall and separated by 120° were three drift fences (5 m long by 25 cm high) made from aluminum flashing. At the outer ends of each fence, two experimental pitfalls were placed—a black trap on one side of the fence and a white trap on the opposite side. We placed a metal screen in the bottom of each pipe to prevent animals from burrowing, and leaf litter was placed in all traps for insulation against cold and to prevent desiccation of captured animals. When not in use, traps were closed using prefabricated drain caps (cost: US $2) that fit snugly into each trap.

The study site was Crosswinds Marsh, a manmade wetland in Wayne Co., Michigan, USA, where we were conducting a post-construction survey of anuran populations. Five arrays, for a total of 15 black and 15 white traps, were placed in various habitats; two arrays were located in wet meadows, two in forested wetlands, and one in an upland woodlot. Pitfalls were checked each morning after 86 trap-nights, between 1 April and 1 June 1997 and 1998. Captured animals were identified to species and immediately released 10 m from the array. Animals were not marked, because a pilot study in 1996 indicated that only 0.3% of marked individuals (N = 896) were recaptured.

TABLE 1. Captures of amphibians and mammals in black vs. white pitfall traps.

Taxon	Number Captured in Black Traps	Number Captured in White Traps	χ^2	P
Anurans				
Bufo americanus	111	45	27.92	<0.001
Rana sylvatica	91	59	7.75	<0.004
Pseudacris spp.[1]	15	6	3.86	<0.05
Other *Rana*[2]	14	26	3.60	>0.05
Mammals				
Sorex cinereus	24	6	10.8	<0.001
Other mammals[3]	13	17	0.53	>0.10

[1]*Pseudacris crucifer* and *P. triseriata*
[2]*Rana catesbeiana, R. clamitans*, and *R. pipiens*
[3]*Blarina brevicauda, Microtus pennsylvanicus, Peromyscus leucopus*, and *Zapus hudsonius*.

We used chi-squared tests to examine the null hypothesis that captures were equally distributed between black and white traps (Leong and Thorp 1999; Yunger et al. 1992). To examine potential differences within species, those with a relatively large number of captures (30) were tested separately . Species with fewer captures were lumped with similar taxa before analysis (Dixon and Massey 1983).

Overall, 135 anurans were trapped in white pitfalls, and 231 were captured in black pitfalls ($\chi^2 = 25.18$; d.f. =1; $P < 0.001$). Only wood frogs (*Rana sylvatica*) and American toads (*Bufo americanus*) were caught in sufficient numbers to allow individual analyses. Black traps captured 54% more wood frogs and 146% more American toads than white traps (Table 1). Low number of captures required lumping two species of *Pseudacris* (spring peeper, *P. crucifer*, and striped chorus frog, *P. triseriata*) together and three large ranids (bullfrog, *Rana catesbeiana*; green frog, *R. clamitans*; and leopard frog, *R. pipiens*). Black traps caught significantly more *Pseudacris* spp., but there was no significant difference in number of captures between black and white traps for the lumped ranids.

The masked shrew (*Sorex cinereus*) was the only mammalian species with a sample large enough to analyze separately (Table 1), and it too was caught significantly more often in black traps. The other four species of mammals were the short-tailed shrew (*Blarina brevicauda*), meadow vole (*Microtus pennsylvanicus*), white-footed mouse (*Peromyscus leucopus*), and meadow jumping mouse (*Zapus hudsonius*). Each was caught in small numbers, and as a group, they showed no difference in capture success between white and black traps.

Although flower-visiting insects appear genetically programmed to prefer certain colors and some mice are attracted to shiny objects (Leong and Thorp 1999; Suplinskas 1987), anurans simply may perceive light-colored traps as different from the substrate and avoid them, or perceive dark traps as potential refugia and enter them. The masked shrews, with their extremely poor vision (Branis and Burda 1994) may be similarly affected, although it is possible that shrews were attracted to the greater number of potential prey (amphibians) in the dark traps. Only the lumped categories of "other *Rana*" and "other mammals" indicated no significant difference between black and white traps (Table 1). However, the other mammals are larger (15–60 g) than the masked shrew (3–5 g; Kurta 1995), and the other ranids are typically larger and/or more agile than the wood frog or American toad (Harding 1997). Vogt and Hine (1982) noted that large anurans are less frequently caught in pitfalls, and the lack of an effect of color on larger mammals and anurans in our study simply may reflect the ability of larger animals to avoid capture.

A variety of ecological studies require the capture of animals. Our study shows that some anurans and shrews are captured significantly more often in pitfalls with a black interior than those with a white interior. Biologists who wish to maximize the number of individuals that are captured during a monitoring study should consider this bias when selecting their trapping protocol.

Acknowledgments.—Funding was provided through a contract between the Wayne County Department of Airports (CIP WL-001) and JJR, Incorporated. C. A. Unger and M. James aided with field work. J. Gilliam and P. Bednekoff provided useful references.

Testing Skeletochronology in Black Tegu Lizards (*Tupinambis merianae*) of Known Ages

CHRISTIAN F. DUARTE VARELA[1]
and
MARIO R. CABRERA[2]
Cátedra de Anatomía Comparada, Universidad Nacional de Córdoba
Vélez Sarsfield 299, (5000) Córdoba, Argentina

[1] *e–mail: chrislio@arnet.com.ar*
[2] *CONICET Researcher. Author to whom correspondence should be addressed; e–mail: mcabrera@com.uncor.edu*

The relevance of age determination resides not only in the need to know how long an organism lives, but also the age of important life events, such as sexual maturity. The reproductive periodicity or the time interval between the production of offspring also is related to age (Zug 1993).

The technique of skeletochronology allows research on maturation by scoring the periods of active growth with alternate periods when the growth process is very slow (Castanet 1978). This seasonal characteristic, evident in the bone tissue, is observed as concentric rings called LAGs (Lines of Arrested Growth) .

One of the first applications of skeletochronology in lizards (scincids and varanids) was accomplished by Peabody (1961). In the green iguana (*Iguana iguana*), Zug and Rand (1987) reported three basic assumptions: 1) there is a period of active growth, followed by a period of arrested growth, leaving distinctive cyclic marks in the bone; 2) each one of these marks indicates one year's growth; 3) where these marks have been lost due to bone remodeling, the number of lost rings can be estimated from the quantity and dimension of the remaining marks (Zug and Rand 1987).

The purpose of this research was to verify the effectiveness of skeletochronology with the black tegu *Tupinambis merianae* [populations formerly assigned to *T. teguixin*, see Avila Pires (1995)], by comparing ring counts to known ages of individuals.

Materials and Methods.—The samples comprised of *Tupinambis merianae* from a commercial breeding facility. They were captive raised under a semi–controlled environment, with natural photoperiod and temperate seasonal conditions. The lizards underwent hibernation from April to mid–September, each year. A balanced diet, mimicked from those in the wild, was provided. Known–age specimens were used, ranging from one to twelve years. Humeri from the right forelimb were removed from sacrificed individuals. In live specimens, the second and third phalanges from the fourth toe of the right hind foot were surgically removed. Afterwards, wounds were treated with iodine–90% ethanol, and animals were immediately returned to their respective stockyards.

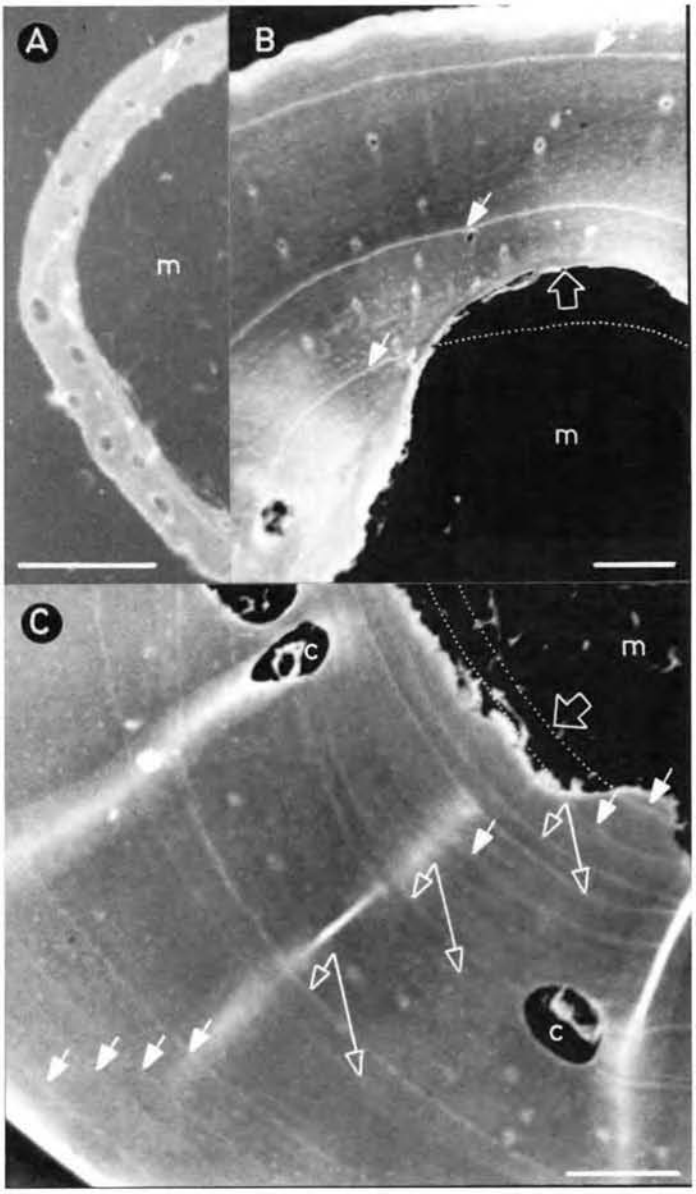

FIG. 1. Cross–section through diaphyseal level of phalanx (A), and humerus (B and C) of *Tupinambis merianae*. (A) One year old specimen; (B) three years old specimen. A marked bone resorption is indicated by the white arrow. The first LAG trait was restored by following the fragment of LAG near the marrow cavity; (C) ten years old individual. First two LAGs restored. Each black arrow indicates a LAG; little white arrows indicate doubled LAGs; big white arrow points to resorption zone; c = canal; m = marrow cavity. Scale bar = 0.2 mm.

A total of 17 humeri and 30 phalanges from randomly captured animals were obtained. The study material was fixed in a 10% buffered formalin solution, decalcified in 5–10% nitric acid, and embedded in paraffin wax. In order to count bone rings, 10 µm serial permanent sections were mounted on glass slides and stained with Ehrlich´s hematoxylin and eosin.

LAGs were counted using a microscope at 5x, 10x, and 40x magnification, several sections of each bone were examined. The microscopic interpretation was performed by two independent readers who, in all cases, did not known the actual age and sex of

TABLE 1. Analyses of humeri and phalanges of *Tupinambis merianae* individuals. Known age (in years) and estimated age (in number of LAGs counted), sex (M = male, F = female) and snout-vent length (SVL) in cm, C.N. = collection number.

the individuals under study. The known–age data and counted LAGs (the estimated age), were compared.

Results and Discussion.—The LAGs are seen as haematoxylinophilic, concentric, regular lines. In every one–year–old specimen, a single thin LAG was present. Tegu lizards hatch from mid–January to late March at this latitude. Our youngest specimens were 13 months old, and thus had undergone one winter season. In these individuals, evidence of a LAG formed at hatching was not observed (Fig. 1A). Smirina (1974) described two LAGs in one–year–old individuals of *Lacerta agilis*, one formed at during their summer hatching, and another representing their first winter latency.

Stained and distinct LAGs were counted, although some were not necessarily complete (Fig. 1B). The presence of double LAGs in *T. merianae* was interpreted as a temporary interruption of the hibernation period. Growth is arrested again when latency conditions return, thus forming two consecutive LAGs. The gap between them is narrow but they can be easily distinguished from single LAGs (Fig. 1C). According to Zug and Rand (1987), difficulty in LAG counting is caused not only by loss of early LAGs, but also by the presence of supernumerary lines. Castanet (1978) explained the presence of double and triple LAGs in terms of "arrêt – reprise – arrêt" (arrest – resumption – arrest) during the same winter season. Supernumerary lines have been described by Zug and Rand (1987), but did not occur in our study.

Resorption of tissue at the perimeter of the marrow cavity was seen in almost all of the bone sections. This endosteal resorption partly masked the interpretation of LAGs. In such cases, age was estimated upon identifiable remaining LAG fragments (Fig. 1 B, C). Comparison of LAG counts between the two observers resulted in 28 matching interpretations and 19 differences. After adjustment with actual age, we reduced the discrepancies to eight misinterpretations. The coincidence between known–age data and estimated–age data was 83% (Table 1). Known–age and estimated–age data linear regression analyses showed a significant relationship for both humeri and phalanges (Fig. 2).

LAG identification was somewhat easier in humeri than in phalanges. In the latter however, which accounted for 63.8% of the samples, the interpretation of LAGs was always possible. The use of phalanges is highly recommended because it prevents sacrificing animals, and allows monitoring of the individual's growth in subsequent years.

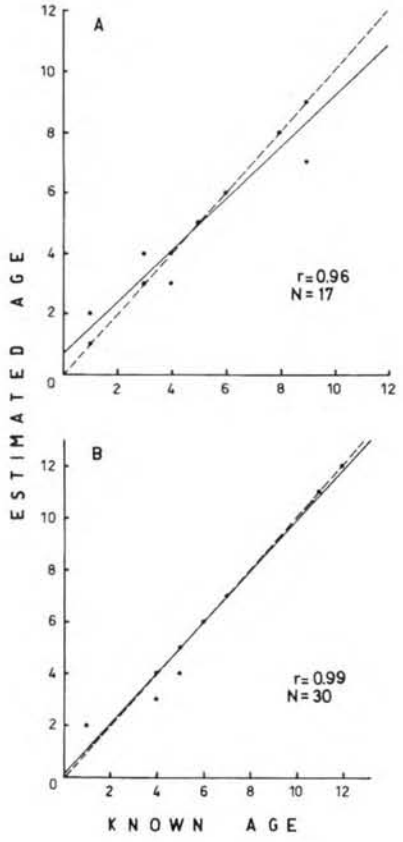

FIG. 2. Linear regression analyses for humeri (A), and phalanges (B), of *Tupinambis merianae*, known age vs. estimated age based upon LAG counts. The dashed line indicates the one–to–one relationship expected if the age estimators are valid, and the continuous line the adjustment between the two variables.

Castanet and Roche (1981) noted that in every skeletochronological study it is critical to work on diaphyseal sections because in metaphyseal zones the bones tend to ovalate. Important remodeling processes occur during growth, resulting in a "drift" of the bone and marrow cavity (Enlow 1969). Furthermore, Castanet and Roche (1981) pointed out that early LAGs never disappear at diaphyseal zones. Our results concur with these authors; LAG counts in *T. merianae* at the metaphyseal level were obscure due to internal structure, but at the diaphyseal level LAGs could easily be interpreted.

The power of skeletochronology to estimate age of animals with cyclic growth has been proven repeatedly (e.g., Castanet et al. 1988; Francillon–Vieillot et al. 1990; Patón et al. 1991; Sagor et al. 1998; Zug and Parham 1996). However, it is probable that the skeletochronological technique diminishes in efficacy when determining age in older specimens, due to the osseous remodeling process (Castanet 1978). In our samples the individual LAG counts and age determination was possible for all specimens. Therefore, we find the technique accurate for specimens up to twelve years old. These results also are encouraging for future research with older individuals.

In conclusion, we confirm the utility of skeletochronology to determine age in *Tupinambis merianae*. LAGs represent an accurate record of the individual's growth process, allowing estimation of age, as well as of interruptions of hibernation during growth. Likewise, skeletochronology is a suitable tool to help monitor tegu lizards that are hunted, as it allows verification of age of trapped animals, and design of capture–mark–recapture and population dynamics projects.

Acknowledgments.—Thanks to Mirian Bulfon and Liliana Giraudo for providing bibliography, to Aldo Bonalumi for technical facilities, and to Gladys Sala for photo–lettering and drawing of Figure 2. Special thanks to Miguel Bartolomé who allowed us to obtain bone samples from his breeding place "Quebracho," in Agua de Oro, Córdoba province, Argentina. Comments by Brian Bowen and one anonymous reviewer are greatly appreciated.

Keys to Partial Mammals: A Method for Identifying Prey Items from Snakes

JOSHUA RYAN WHORLEY*
Museum of Vertebrate Zoology and Department of Integrative Biology
University of California at Berkeley
Berkeley, California 94720-3160, USA

**Present address:*

Researchers study the diet of snakes to address a wide range of topics, including optimal foraging (e.g., Arnold 1993; Shine 1991), the evolution of body size and morphology (e.g., Greene 1983; Pough and Groves 1983), interspecific niche partitioning (e.g., Reynolds and Scott 1982; Rodriguez-Roblez et. al. 1999), and intraspecific resource partitioning (e.g., Macartney 1989; Shine 1986). The usefulness of such studies depends upon precise prey identification, which may be challenging if the snake species under study has eclectic food habits and/or consumes prey from multiple orders or classes (see Greene 1997 for an overview of diet breadth).

Identifying half-digested mammals remains a problem for many researchers interested in the feeding ecology of snakes. Because snakes usually ingest prey headfirst (Greene 1989; Seib 1984), the diagnostic skulls and teeth of mammalian prey are digested first, making identification difficult. Occasionally teeth may remain in the stomach—still rooted in the mandible or dentary—and in rare cases, salvaged prey items may even be largely undigested. However, stomach contents collected from museum specimens often consist of no more than a set of hind feet and a tail. Not surprisingly, researchers often list these disintegrating contents only as "unidentified mammal" or "rodent." Though this provides some information, prey identification to the class, ordinal, or even familial level may be too imprecise to address the question being asked. If one is testing specific hypotheses of foraging theory or prey choice, for example, identification to at least generic level is necessary to avoid overestimates of diet breadth or incorrect conclusions about predator behavior or community dynamics (Greene and Jaksic 1983).

To solve the problem of accurate prey identification, some workers have relied on keys detailing the length, width, and microstructure of dorsal guard hairs. However, this method is time consuming and sometimes inconclusive. Hair analysis demands that one find, cross-section, and mount guard hairs retrieved from each prey item needing identification. It also requires a published key or collection of pre-mounted guard hairs covering the geographic area of interest. Few such keys exist, and rather than focusing on all mammal species inhabiting a particular life-zone or biome, they are often state or region specific (e.g., Mathiak 1938; Mayer 1952; Williams 1938). Consequently, unless the range of a particular snake species is extremely limited, or the diet study focuses only on a selected population (e.g., Macartney 1989; Wallace and Diller 1990), one key may not provide all the hair sample material necessary for comparisons. In addition, finding a dorsal guard hair within the recovered prey remains is often impossible—especially if all that remain are hind feet and tail. If stomach contents do not include teeth or soft tissue, one must use hair structure to identify mammalian prey. But for samples that do include soft tissue, a more efficient, precise, and reliable method is available.

Hindquarters of prey are often present in snake stomachs, and are easier to find and manipulate than individual hairs. Because they are highly variable among genera, hind feet and tails provide excellent characters upon which to base a dichotomous key. The plantar tubercles (foot pads) of rodent hind feet often vary in number, degree of development, and arrangement on the foot (Fig. 1A, 1D). Hind feet may also vary in length or number of toes, and in density and color of fur covering their ventral surface (Fig. 1B). Tails differ in a number of categories including color pattern, dorsal and/or ventral striping, pelage thickness, and expansion at the tip (Fig. 1C). Because hindquarters are the last portions attacked by digestive enzymes, these variant traits are dependably intact.

To build a key, first compile a list of the small mammal families occurring within the geographic and elevational range of the snake species under study. Use an encyclopedic mammal reference (e.g., Hall 1981; Lawlor 1979; Nowak 1991) to quickly identify all the possibilities. Use one that provides concise accounts of the general features that characterize each mammal family. Lawlor's (1979) *Handbook to the Orders and Families of Living Mammals* is optimal because it covers morphological features, and general habits and habitat preferences, and also identifies which biomes particular mammal families occupy.

After using Lawlor or a similar text, refine the mammal list to genus and species by consulting a regional checklist or field guide detailing mammal life-histories, appearance, and ranges. Dozens of field guides exist for North American mammals. Each has advantages and disadvantages, and one should use two or three in concert to gather a complete set of information. In contrast to North America, other continents or regions may completely lack field guides or checklists of local mammal fauna. This may not be problematic though, as many museums are now placing their specimen databases on the World Wide Web (e.g., Museum of Vertebrate Zoology (MVZ); California Academy of Sciences (CAS); United States National Museum (USNM), Australian Museum, Peabody Museum). Most online catalogues are accessible and easy to navigate, and provide a variety of searchable fields (e.g., MVZ, Peabody Museum, USNM) including county, state/province, and geographic area. If a museum has collected mammal specimens from the geographic region of interest, generating a list of probable prey items from their online museum records should be fast and inexpensive. Such records may also have links to collectors' notes (e.g., MVZ), which may include valuable information on relative abundance and habitat requirements.

Next, collect mammal field guides or checklists with drawings of teeth. Use teeth to identify prey items whenever they can be found in mammal remains. (One can immediately identify a prey item to genus using tooth morphology, and usually to species with the additional aid of a range map.) Teeth may be loose in the snake's stomach, still rooted in the mandible or dentary, or encased in a clump of fur (Rodriguez-Robles et al. 1999). If no drawings exist, sketch your own to complement your dichotomous key (see below).

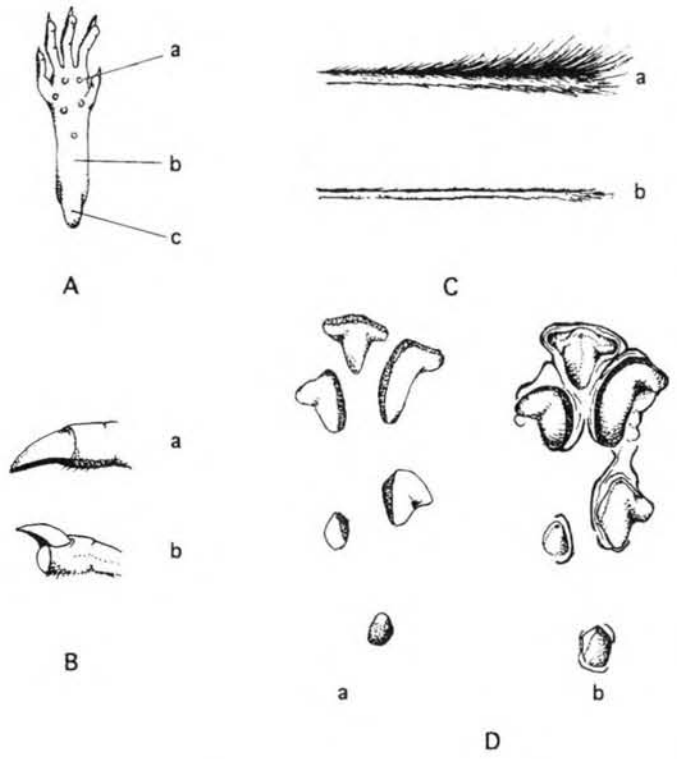

FIG. 1. Variable traits of mammalian hind feet and tails. A) Rodent foot anatomy: (a) tubercles, (b) sole, (c) heel. B) Toe anatomy of rodent species: (a) *Thomomys* species, (b) other species. C) Tail anatomy of rodents: (a) crested, (b) penicillate. D) Plantar tubercle anatomy: (a) pointy and wedge-shaped, (b) bulbous and layered.

The final step is to construct a dichotomous key by referring to alcohol-preserved mammal specimens. Gather representative specimens from each potential prey species on your list, then separate them by identifying unique hind foot and tail characteristics. Some species of the same genus are indistinguishable based on hind foot anatomy and dimensions alone. In such cases, you'll have to rely on a combination of range maps and snake specimen capture/locality data to determine probable prey species.

After completing an inclusive key, briefly study the morphology of those small mammals that share habit and habitat with the snake under study. Familiarity with morphology will facilitate rapid identification of rodents that commonly appear in snake stomachs, and preclude consistent reliance on a key. Just knowing the substrate (e.g., sand dunes, hardpan and gravel, or rock and boulder outcrops) and vegetation types present—both in terms of physical structure/cover, and as a potential food source for rodents—will provide insight into the small mammal fauna of the area. For example, to study the diet of the Mojave rattlesnake, *Crotalus scutulatus*, you would determine from Lawlor that heteromyids (kangaroo rats, kangaroo mice, and silky and spiny pocket-mice) are the most common nocturnal rodents inhabiting desert creosote/sagebrush flats and sand dunes, the usual habitat of those snakes. However, to study the food habits of the speckled rattlesnake, *Crotalus mitchellii*—from the same desert—would require close examination of the cricetine rodents (wood rats, white-footed mice, and harvest mice), as they prefer the higher elevation rocky canyons and outcrops where *C. mitchellii* is usually found.

Below is a sample key based on hind foot and tail characteristics of the potential prey items of the Mojave rattlesnake (*Crotalus scutulatus*). Because the key includes all rodents and rabbits within the rattlesnake's range, it avoids artificial boundaries and is really a key to the small mammals of that region. By using hind foot and tail characteristics to identify the genus of each prey item, and then consulting field guide range maps to determine which species it could belong to, I unambiguously identified 62 of 73 items from Mojave rattlesnake stomachs (Whorley, unpubl.).

Key to Potential Mammalian Prey of the Mojave Rattlesnake (*Crotalus scutulatus*)

1. Ventral side of hind feet woolly. Foot pads (plantar tubercles) hidden by fur ..... See 2
1a. Hind feet lightly furred or naked ventrally. Plantar tubercles naked. ..... See 5
2. Tail short and puffball. Hind feet stocky; no dusky stripe ..... See 3
2a. Tail long and tufted. Hind feet slender; distinct dusky stripe on ventral side ..... See 4
3. Hind foot < 100 mm in length ..... ***Sylvilagus audubonii***
3a. Hind foot > 112 mm in length ..... ***Lepus californicus***
4. Hind foot with 4 large toes. Fifth toe is vestigial and located halfway up inside of hind foot; usually just the claw is visible. ..... ***Dipodomys*** species
4a. Hind foot with 4 large toes, no vestigial fifth toe. ..... ***Dipodomys merriami***
5. Four plantar tubercles arranged symmetrically about long axis of hind foot. Sole of hind foot densely furred from heel to tubercles. ..... See 6
5a. More than four plantar tubercles arranged asymmetrically about long axis of foot. Sole of feet sparsely furred or naked from heel to tubercles ..... See 8
6. Fur on tail and hind feet thick, coarse, and long. Hind feet longer than 28 mm; tail longer than 54 mm ..... See 7
6a. Fur on tail and hind feet fine; short and sparse on tail. Hind foot length less than 25 mm. Tail stout and less than 54 mm; proximal dorsal 1/3 reddish-brown; distal 2/3 and entire ventral side pale. ..... ***Onychomys*** species
7. Dark brown, gray, or black fur on underside of feet; dark skin. Tail bushy, flattened distally, and sometimes striped. ..... ***Ammospermophilus*** species
7a. Pale tan, or brown fur on underside of feet; pale skin. Tail somewhat expanded distally, rounded, not flattened. ..... ***Spermophilus*** species
8. Claws thick, protruding from front of toes (Fig. 1B). ..... ***Thomomys*** species
8a. Claws thin, arching from top of toe (Fig. 1B) ..... See 9
9. Six or fewer poorly developed, hard, circular plantar tubercles. ..... See 10
9a. Six well developed, protruding, sometimes bulbous or wedge-shaped plantar tubercles ..... See 12
10. Tail with no distal penicillation or crest. First (outermost) and fifth (innermost) digit of right hind foot (RHF) about same length and barely reaching the base of digits 2 and 4. ..... ***Sigmodon*** species
10a. Tail with distal penicillation or crest. Fifth digit of RHF noticeably longer than first digit, and reaching well past the base of fourth digit ..... See 11
11. Tail crested (Fig. 1C); sole and heel of hind feet naked. ..... ***Chaetodipus*** species

11a. Tail penicillate (Fig. 1C); fur encroaching onto heel of hind feet. ..... ***Perognathus*** species

11b. Tail penicillate; sole and heel of hind feet naked. ..... ***Peromyscus eremicus***

12. Tubercles pointy and wedge-shaped (Fig. 1D) ..... See 13

12a. Tubercles bulbous and stacked (Fig. 1D) ..... See 14

13. Hind feet < or = 15 mm. tail 34–53 mm ..... ***Baiomys tailori***

13a. Hind feet longer than 15 mm. tail 55–96 mm. ..... ***Reithrodontomys megalotis***

14. Tail bicolored with distinct dorsal stripe; darker above than below. ..... ***Peromyscus*** species

14a. Tail unicolored ..... ***Neotoma*** species

Acknowledgments.—I thank Harry W. Greene, Javier Rodriguez-Robles, and Z Morgan Benowitz-Fredericks for support and helpful comments on my draft manuscript, and Robert P. Reynolds and an anonymous reviewer for suggestions and critiques. I thank J. L. Patton (Museum of Vertebrate Zoology) and J. G. Kenagy and J. Rozdilsky (University of Washington Burke Museum) for access to mammal specimens.

Use of Fluorescent Powder to Track Horned Lizards

RICHARD C. STARK

e-mail: foxstan@okstate.edu

Researchers have successfully used fluorescent powder to track small mammals (Lemen and Freeman 1985) and tortoises (Blankenship et al. 1990; Butler and Graham 1993; Keller 1993). Fellers and Drost (1989) used the method to track island night lizards, *Xantusia riversiana*, and suggested that the powder may work better on lizards with keeled scales. Here, we report the successful use of fluorescent powder to track Texas horned lizards, *Phrynosoma cornutum*. We hope that this method can be used on other reptiles with spiny integuments.

Over the past several decades, Texas horned lizards have decreased in both range and abundance in Oklahoma (Carpenter et al. 1993), as in Texas (Donaldson et al. 1994), and scientific research on this species in Oklahoma has been limited. In fact, the only study conducted on this species in Oklahoma was a population census (Carpenter et al. 1993). Future investigations into the ecology of Texas horned lizards in Oklahoma may be necessary to help conserve this species.

We used fluorescent powder to track Texas horned lizards on two study sites in north-central Oklahoma that we named Antique Field (AF) and South Field (SF). The fluorescent powder method was used to obtain area and habitat use data because it allowed us to obtain exact information about the movements of the lizards.

We located horned lizards by visual searches and toe clipped captured individuals for future identification. Following the methods of Fellers and Drost (1989), captured lizards were then dipped into a plastic bag containing the fluorescent powder. The lizards were held by the head while being dipped so that the powder did not get into their eyes, nares, and ear openings. Additionally, we gently rubbed the powder on each lizard to make certain the powder adhered well, and that the lizard was well covered.

Dipped lizards were released at the place of capture, and that spot was marked with a survey flag. That night, with the aid of a portable ultraviolet lamp, we traced the trail of powder left by the lizard—all the way to the current position of the lizard if possible. We placed survey flags in the ground at approximately every five meters on the trail and also at the end of the trail where lizards were relocated. The flags were used to estimate total daily distance moved (Tables 1 and 2), as markers to take microhabitat measurements, and to determine the x-y coordinates of lizard locations (grid systems were set up at each study site using survey equipment).

We purchased powder in 1998 from Radiant Color (2800 Radiant Avenue, Richmond, California 94804, USA) for US $12 per one-pound can. The colors we used were pink, chartreuse, orange, green, and blue. Lizards dipped in chartreuse, pink, and green left bright, distinctive trails. Pink and orange looked very similar under ultraviolet light, as did green and chartreuse. The blue powder was difficult to find after about 15 m, and is therefore not recommended.

Our lamp was a portable, rechargeable, longwave ultraviolet lamp. Each charge lasted for about five hours, and the lamp could be recharged 500 times. We purchased the lamp from Fisher Scientific (http://www.fisher1.com) in 1998 for US $215.

The fluorescent powder method was used in two field seasons, 1998 and 1999. Success with the method improved with practice, and here we briefly report results gathered only in the second season. At both sites, we dipped and released lizards at various times of day. Contrary to our expectations, distances traveled (standardized as $(x_i - \bar{x})/SD$, where x_i is distance traveled by an individual, and $\bar{x}$ and SD are the mean and standard deviation of the age/sex/site class to which that individual belongs) did not vary with the time of day when the lizard was dipped and released ($r = 0.02$, $df = 72$, $p > 0.50$). In other words, lizards marked and released early in the day did not travel further than those marked and released later in the day, despite having more time to do so.

At SF, 15 lizards (7 males, 6 females, 2 juveniles) made 28 tracks between 28 May and 25 July, 1999. We successfully tracked a lizards to where they slept (end of the day's trail) 93% of the time. Unsuccessful attempts to track a lizard to its sleep spot were usually not due to the length of a trail, but rather to confusion caused by trails of the same color overlapping several times. Daily (untransformed) distance traveled was not significantly different for males, females, and juveniles (Kruskal-Wallis Test, $H = 3.7$, $df = 2$, $p > 0.10$). Maximum daily distance traveled was 55 m (Table 1).

At AF, 25 lizards (7 males, 10 females, 8 juveniles) made 46 tracks between 8 May and 25 July, 1999. Lizards were successfully tracked to their sleep spots 81% of the time. To better compare distances traveled by the age/sex classes at the two sites, we divided tracks at AF into those made on or before 28 May and those made after 28 May. Before 28 May, daily distance traveled was significantly different among males, females, and juveniles (Kruskal-Wallis Test, $H = 11.66$, $df = 2$, $p < 0.003$), with males

TABLE 1. Daily distance (m) traveled by Texas horned lizards at SF and AF after May 28.

Site	Class	N	Range	Mean	SD
SF					
	Female	14	15–50	29.3	12.2
	Male	10	10–55	27.0	14.2
	Juvenile	4	5–35	16.3	13.1
AF					
	Female	17	5–95	29.3	32.8
	Male	6	10–95	40.8	28.9
	Juvenile	7	5–35	13.6	10.3

TABLE 2. Daily distance (m) traveled by Texas horned lizards at AF prior to May 28.

Class	N	Range	Mean	SD
Female	7	10–55	31.4	15.7
Male	7	55–225	111.4	67.5
Juvenile	2	5	5.0	0

moving much greater daily distances than females and juveniles (Table 2) even though they were tracked less frequently to their sleep spots during this time (although not significantly less frequently than the other age/sex classes: $\chi^2 = 2.82$, df = 2, $p > 0.20$). Even though time of day when lizards were dipped and released did not influence distance traveled, time of day dipped was not significantly different among age/sex classes (Kruskal-Wallis Test, $H = 0.62$, df = 2, $p > 0.50$). Males also moved greater daily distances than females and juveniles after May 28 (Table 1), but not significantly so (Kruskal-Wallis Test, $H = 4.603$, $p > 0.05$). Maximum daily distance traveled at this site was 225 m, performed by a male lizard prior to May 28 (Table 2).

The large difference in maximum daily distances traveled at the two sites and the fact that daily distance traveled was significantly different among age/sex classes only at AF before May 28 can be explained by the observation that all tracking instances over 100 m at AF were by males in early to mid-May, and occurred before tracking began at SF. Texas horned lizards emerge from brumation in mid-April or early May, and adult males may travel greater daily distances soon after to find mates. After that time, distances moved per day appear to be shorter.

Although this method allows a researcher to obtain information about the exact movements of an animal, and we were often able to record the entire daily movements of a lizard, certain limitations exist. Lizards that tend to stay in the same area can be tracked a limited number of consecutive days because current and recent trails are often difficult to distinguish and may overlap considerably. Thus, it is difficult to track individuals in a small area over an extended period of time unless there is rainfall during that period to help fade old trails. Using a different color of powder each day for one lizard helps to alleviate this problem, but there are a limited number of colors available. Also, only a few animals can be tracked in a small area at one time, or else the trails of lizards dipped in the same color may cross several times, leading to confusion. Perhaps old trails could be "erased" using a small leaf blower or portable water sprayer, although the regular use of these items might alter habitat (food, vegetation, etc.). Finally, the powder can blow off lizards that spend much time in the open on windy days, leading to scattered deposits. Trails show up best in areas of grassy and herbaceous vegetation.

Acknowledgments.—This work was part of a study on the space and habitat use of Texas horned lizards in Oklahoma. Financial support was provided by the Wildlife Diversity Program of the Oklahoma Department of Wildlife Conservation, the Department of Zoology at Oklahoma State University, and the Oklahoma Cooperative Fish and Wildlife Research Unit (Oklahoma State University, Oklahoma Department of Wildlife Conservation, USGS Biological Resources Division, and Wildlife Management Institute, cooperating). We thank ARC Communities and Lambert Construction for allowing us to conduct the study on their properties. We also thank David M. Leslie, Jr., for his useful comments and suggestions, reviewer Gary Fellers for his suggestion about "erasing" old trails, and John Dyer, Matt Sivils, and Joe Hackler for their valuable help in the field.

PVC Sleeves for Attaching Ultrasonic Transmitters to Turtles

TERRY E. GRAHAM

e-mail: tgraham@worcester.edu

During the initial phase of field study of winter behavior and physiology in the common map turtle, *Graptemys geographica*, in northern Vermont, USA, we attached ultrasonic transmitters (Sonotronics model CT82-2) to the carapaces of adult females. We used monofilament fishing line tied to two small stainless steel screweyes screwed into the dorsal surface of the marginals. These plastic-encased cylindrical transmitters measured 16 x 64 mm, weighed 8 g, and had a small hole at each end for attaching them with wire or fishing line. We found that the tags tied on with fishing line were not held tightly against the carapace, and thus risked being caught on submerged snags. In addition, we thought that the monofilament line might break or deteriorate causing costly loss of equipment and time. For these reasons we decided to modify the means of transmitter attachment.

Rather than change to stainless steel wire, which might eliminate the risk of breakage (but not the risk of snagging) we sought an alternative means of transmitter attachment. We decided to glue the transmitters inside plastic pipe of about the same diameter. Inexpensive 3/4-inch (1.9 cm) white PVC pressure pipe, which has an inside diameter (17 mm) slightly greater than the outside diameter of the transmitters, was first cut to length (ca. 5 cm longer

FIG. 1. Transmitter in PVC sleeve bolted directly to the carapacial margin. Note the reasonably tight fit of this unit to the shell.

than the transmitter). Next, a portion of each end of this tube was cut away to leave a flat tab extension. The tabs were drilled to accept stainless steel bolts, for attachment to holes drilled in the marginals of the turtle being tagged. The transmitter was next coated (except for the ends) with multipurpose cement (TITESEAL all purpose, T62-04) and inserted slowly into the PVC tube. After a curing period of 24 h these assembled units were engraved with a rotary tool on the upper side to identify the signal that would be given by the transmitter inside, e.g. 258. The tubing was similarly marked with bold indelible black ink to make a very visible number (Fig. 1). The completed units, which weighed about 35 g, were then bolted to the carapace through two holes drilled in the marginal scutes to the left of midline (Fig. 1) to reduce interference with mating behavior. What resulted was a very durable bond between transmitter and tubing and a solid attachment to the shell. Of seven transmitters attached in this fashion, six were found intact after one year, while only one of eight affixed with monofilament line was located.

Our attachment method could be modified to accommodate data loggers, radiotransmitters, or other small pieces of equipment. Finally, we do not endorse the use of ultrasonic tracking equipment in all situations. It is highly useful in marine habitats and some freshwater situations, but signal attentuation by vegetation, trees, brush, or other debris in seasonally inundated woodlands adjacent to rivers can make it extremely difficult, if not impossible, to locate tagged animals that move into those settings.

Acknowledgments.—We thank Carlos Crocker for help with the initial fastening of transmitters with monofilament line, and Marlin Gregor of Sonotronics for discussion which led to the more effective means of attachment reported here.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 31, Number 1 (March 2000). Submissions should be directed to one of the section editors (contact information located on inside front cover of this issue), as follows: amphibians (Painter); lizards, amphisbaenians, crocodilians, *Sphenodon* (Hauge); snakes and turtles (Butterfield).

CAUDATA

AMBYSTOMA BARBOURI (Streamside Salamander). **REPRODUCTION.** Geographically isolated populations of *Ambystoma barbouri* have recently been verified from middle Tennessee (Scott et al. 1997. Herpetol. Rev. 28:155). Information on the natural history of these populations is limited to a report by Ashton (1966. J. Tennessee Acad. Sci. 41:106–111), who commented on the unusual, stream-breeding habits of *A. texanum* in Davidson County, Tennessee. The Davidson County population discussed by Ashton is thought to be *A. barbouri* rather than *A. texanum* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington. 587 pp.). Here, we report a second breeding stream in the Central Basin of Tennessee and provide information on the timing of reproduction, egg mass size, and hatchling size.

Egg masses and hatchlings were discovered in the southernmost section of Puckett's Creek (35°49'N, 86°28'30"W), in Rutherford County, on 10 March 2000. Puckett's Creek is a first-order stream bordered by a narrow (5–30 m) strip of forest and ca. 1.0 km of field extending either to state roadways or residential housing. The eggs were found attached in a monolayer to the underside of flat rocks located in intermittent pools within the stream course. A single egg mass was collected and transported to the laboratory for rearing and confirmation. Within three days all of these eggs hatched and all hatchlings were measured (N = 51; mean TL ± 1SD = 15.6 ± 1.2 mm). Seventeen additional egg masses were located on 14 March 2000, but several were deteriorating following hatching or dehydration. Clutch sizes were estimated from ten intact masses (eggs per mass: 65, 61, 52, 16, 15, 15, 14, 8, 7, 5). Based on time of hatching and assuming a 29–82 day incubation period (Petranka, *op. cit.*), we estimate that oviposition occurred between late December and mid-February. The Middle Tennessee region is rapidly expanding. Residential construction is currently underway at the north end of Puckett's Creek, approximately 3.0 km from this unstudied population.

PLETHODON CADDOENSIS (Caddo Mountain Salamander) and ***PLETHODON SERRATUS*** (Southern Redback Salamander). **NOCTURNAL CLIMBING ACTIVITY.** Nocturnal surface activity in the plethodontid salamander genus *Plethodon* has been well documented for a variety of species (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.; Spotila 1972. Ecology 42:95–125). Observations on the nocturnal climbing abilities of some members within this genus as well as in other plethodontids, however, have appeared less frequently in the literature (Cliburn and Porter 1986.

CAUDATA

AMBYSTOMA TALPOIDEUM (Mole Salamander). **TIMING OF BREEDING**. Paedomorphosis occurs when adult salamanders retain a larval morphology. *Ambystoma talpoideum* is a facultatively paedomorphic species found throughout the southeastern United States. In South Carolina populations, paedomorphic *A. talpoideum* breed primarily in October and November, ca. 6 weeks earlier than metamorphic individuals (Scott 1992. Am. Midl. Nat. 129:397–402; Krenz and Sever 1995. Herpetologica 51:387–393). Paedomorphic breeding wanes in January, while metamorphic courtship may continue until early March (Whiteman, unpubl. data). Here I describe evidence of breeding occurring in both morphs of *A. talpoideum* in mid-March, much later than has presently been recorded.

During 14 March–19 April 1999, I captured 13 paedomorphic (7 male; 6 female) and 3 metamorphic (2 male; 1 female) *A. talpoideum* in a wooded, permanent cattle pond on the Ridley Farm property in western Calloway County in western Kentucky. Within the first week (14–21 March), two paedomorphic (SVL 58 mm female; 60 mm male) and two metamorphic (SVL 60 mm male; 50 mm male) individuals were breeding. Salamanders captured after this time were no longer breeding, as cloacal swellings had receded. Using the Lincoln-Peterson mark-recapture equation (Pollock et al. 1990. Wildl. Monogr. 107:1–97), I estimated the paedomorphic population to be ca. 20 individuals.

Finding two large, actively-breeding paedomorphic *A. talpoideum* during March is unusual. In a study of South Carolina *A. talpoideum*, Whiteman (unpubl. data) found that large paedomorphs bred in December and early January, but only small, recently mature individuals bred into early February. Thus, either this Kentucky population represents an extension of the normal breeding time of paedomorphic *A. talpoideum*, or the individuals I captured had only recently matured, although at an enlarged size.

In support of the first hypothesis, terrestrial *A. talpoideum* breed until mid-February in southern Louisiana (Shoop 1960. Tulane Stud. Zool. 8:65–82), and through March in northern Louisiana (Hardy and Raymond 1980. J. Herpetol. 14:327–335), suggesting that further increases in latitude may prolong paedomorphic breeding as well. Although *A. talpoideum* can mature at 30 mm SVL, they sometimes delay maturity until larger size is reached (Semlitsch 1985, Oecologia 65:305–313), providing support for the second hypothesis. Only further study will allow proper testing of these alternatives.

I thank Dr. Ridley for access to his ponds, R. Cates and M. Dotson for field assistance, and H. Whiteman for manuscript revision.

DESMOGNATHUS OCOEE (Ocoee Salamander). **REPRODUCTIVE FAILURE**. Beginning in 1994, I have monitored oviposition by female *Desmognathus ocoee* in crevices in wet cliffs associated with small streams in Banks County, Georgia, USA. A pair of small cliffs (combined area ca. 1.5 m^2 of wet cliff face) marks the headwaters of a first-order stream and is normally kept wet by a thin, flowing sheet of water. In every year of this study prior to 1999, females successfully oviposited in narrow, wet crevices at this site. Typical of this species' nesting behavior (Forester 1981. J. Herpetol. 15:29–34), each female established residency at a nesting site prior to oviposition, and then remained there until her eggs hatched. Hatching occurred an average of 36.1 (range = 32–39 for 7 clutches) days following egg-deposition. Larvae escaped into the stream by swimming across the thin sheet of water across the cliff face. Oviposition began every year by the second week of August, with the earliest new clutch laid 13 July 1996 and the latest new clutch 15 August 1995. As many as eight different females and their associated clutches have been observed on these cliffs at one time.

This area experienced drought in 1999 and the cliffs were completely dry by late July. During this time, the stream surfaced 88 m downstream of its normal point of origin. I visited the site regularly (at maximum intervals of every four days) from 10 August to 2 October 1999. Four gravid females, whose eggs could be seen through their venters, were initially observed occupying crevices. The first measurable rain (>2 cm) of August fell 20–24 August and kept the cliffs wet for several days. On 29 August one of the females had laid 6 eggs. Ova could still be seen through her venter, indicating that she laid only part of her complement of eggs . By 2 September the cliffs were again dry, and the eggs were gone. The female remained in the crevice and was last seen on 26 September. By 30 September she had abandoned the site. None of the other females laid clutches, and by 2 October all but one had abandoned their nesting sites. On 2 October the last remaining female was collected, preserved, and subsequently dissected. She measured 43.5 mm SVL and contained 12 enlarged ova. This specimen has been deposited in the University of Georgia Museum of Natural History (UGMNH 44321).

Indications are that the subpopulation associated with this set of small cliffs suffered total reproductive failure. Because females breed annually (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Inst. Press, Washington, D.C.), the loss of a year's reproductive effort probably has a significant negative effect on fitness. Appalachian streams are generally thought to represent stable environments (Bruce 1985. Copeia 1985:847–854). However, fluctuation in levels of available moisture, particularly in headwater areas, may provide a previously unconsidered source of environmental instability. Relative instability of these areas in turn may influence the evolution of life-history traits in a way to minimize fitness loss (Stearns 1992. The Evolution of Life Histories, Oxford Univ. Press, New York).

EURYCEA CIRRIGERA (Southern Two-lined Salamander). **LARVAL PERIOD/ SIZE-CLASS DETERMINATION**. Little has been documented regarding the life history of *Eurycea*

cirrigera, a sibling species of *E. bislineata*. This species was first recognized in West Virginia by Jacobs (1987. Herpetologica 113:202–204). During a four-month period from July–October 1992, data were collected in Keeney Creek, Fayette County, West Virginia, USA, that indicated there are three distinct larval periods, or year classes, in *E. cirrigera*. The size groups observed were 6–11.5 mm, 13.2–16 mm, and 20–27.2 mm SVL. The first size-class represents newly hatched individuals, the second, 2nd year larvae, and the third, 3rd year larvae (juveniles). These data coincide with the size-class means observed for *E. bislineata* of 9.18, 20.04, and 25.25 mm SVL reported by Duellman and Wood (1954. Copeia 19542:92–98). In contrast to its sibling species in southern populations that have a 12–14 month larval period (Bruce 1986. Herpetologica 42:149–155), *E. cirrigera* has a much longer larval period of ca. 3 years in West Virginia. Similar to *E. bislineata*, *E. cirrigera* also experienced downstream drift and were found to have low surface density when surface density of *Desmognathus quadramaculatus* was high. Adults and juvenile *E. cirrigera* were abundant from the study area during summer and early fall, as was true of *E. bislineata* in previous studies (Kleeberger 1984. Ecology 65:1849–1856). The surface density of larvae began to increase with the return of adult individuals at the end of the study period (mid-October) as water temperature decreased. In summary, the observations reported herein support the hypothesis that *E. cirrigera* has a similar, if not identical, life history as that of its sibling species, *E. bislineata*.

PLETHODON CINEREUS (Red-backed Salamander). **INTRASPECIFIC AGGREGATION.** The red-backed salamander, *Plethodon cinereus*, is a terrestrial species found in late-successional deciduous forests from Ontario and Newfoundland in the north, to Indiana and North Carolina in the south (Behler and King 1979. The Audubon Society Field Guide to North American Reptiles and Amphibians. Alfred A. Knopf, Inc., New York. 743 pp.). Several studies have shown that this species is territorial and solitary in its southernmost range. Research carried out in both a laboratory setting and natural habitats has demonstrated that both males and females actively defend areas against intruding conspecifics and usually expel such intruders aggressively (Jaeger 1981. Am. Nat. 117:962–974; Mathis 1990. Anim. Behav. 40:953–962). Anthony et al. (1997. Behaviour 134:71–88) believe that aggressive behavior among plethodontid salamanders is a crucial component of their social interactions. Conversely, a recent study suggests that red-back salamanders in the northern part of their range do prefer to aggregate in both natural and laboratory settings (Quinn and Graves, *in press*. Ethology 105). With the exception of this recent study, research and observations concerning geographic variation in *P. cinereus* social behavior is lacking.

On 25 September 1999, five *Plethodon cinereus* were found aggregated within the same fallen log in a late-successional deciduous forest at Big Bay, Marquette County, Michigan, USA. The largest aggregations observed in natural habitats rarely exceed two animals (Quinn and Graves, *op. cit.*) and groups of five have never been reported. All salamanders were within 1-3 cm of all the other salamanders in the group. The log was ca. 1.2 meters in length and 15 cm wide. Fallen logs of equal size were abundant at the site, however all cover objects turned within a $10m^2$ area appeared to be unoccupied by conspecifics. Following their discovery, salamanders either attempted to escape or remained stationary. Escape behaviors consisted of crawling further into the log or moving towards the forest floor away from the log. Mating activity is believed to occur in the fall (October through December), where males actively seek females (Harding 1997. Amphibians and Reptiles of the Great Lakes Region. The University of Michigan Press, Ann Arbor. 378 pp.). Breeding aggregations of this size have not been reported, and aggregations of more than two red-backed salamanders in any other context are rarely encountered. A sufficient explanation for this aggregation cannot be speculated given the readily available cover objects, moisture, and prey items. This observation leads us to believe that geographic variation in territorial behavior may occur in plethodontid salamanders.

ANURA

BUFO BAXTERI (Wyoming Toad). **PREDATION.** Endangered species are often characterized by small, isolated populations with a high risk of extinction from stochastic events (i.e., unfavorable weather, habitat destruction, increased depredation). Local and even broad scale population declines or extinctions due to increased depredation are often attributed to introduced predators. It is not often that a naturally occurring predator-prey relationship results in the extinction or extirpation of a prey population

The Wyoming toad, *Bufo baxteri*, thought to be a glacial relict of the Canadian toad, *Bufo hemiophrys*, historically existed only in the Laramie River Basin of Albany County, Wyoming, USA. In the mid-1970s, the entire population experienced drastic declines in abundance for unknown reasons and was listed as federally endangered, after it was thought to be extinct, in 1984. Later, a wild population was found at a single, small, aquifer- and irrigation-fed seepage lake (Mortenson Lake) in the basin. The population was estimated to be fewer than 50 adults during a fall 1999 survey by the U.S. Fish and Wildlife Service.

A widespread captive-breeding program has been important in the management of this population and involves 12 zoos across the nation and two U.S. Fish and Wildlife Service facilities. For almost 8 years, the captive-breeding program has allowed reintroduction of tadpoles and toadlets to Mortenson Lake to help maintain the population because there was no natural reproduction between 1991 and 1998. During the 1998 and 1999 breeding seasons, there were at least six fertile egg masses produced in the wild.

During the summer of 1998, we implanted radio transmitters in nine Wyoming toads captured at Mortenson Lake. The toads were followed from 1 August until 7 October. By the second week of September, six remaining toads with active transmitters and an unknown number of unmarked toads congregated at a very small area where suitable hibernacula were suspected to exist. The area

was a ditch adjacent to the shore of the lake. A small berm bordered the north side of the ditch and the slope of a hill bordered the south side of the ditch to form raised topography suitable for hibernacula. Congregation at hibernacula is typical of the species, as well as the closely related *Bufo hemiophrys*, and usually does not last long before freezing temperatures force them underground for the winter. During this fall congregation period, predators killed the six toads with active transmitters the last week of September. Of the other three that had transmitters, one was killed by a predator during the last week of August, a second died of a fungal infection (*Basidiobolus ranarum*) as diagnosed by the state veterinary laboratory, and the third was lost due to transmitter failure (the toad was visually identified, though no signal was being transmitted).

Since management of the Wyoming toad began, it was thought that the only significant cause of mortality threatening the population was *Basidiobolus ranarum* and *Aeromonas hydrophila*, a saprophytic fungus and bacterium, which causes micotic dermatitis and "red leg." Evidence at the kill sites of each toad suggests mustelids as the primary predators. The transmitters were left behind with tooth-marks in them as well as footprints at the sites. Indicative of mustelids was the fact that the entire carcass was consumed in each case. Other mammalian and avian predators are known to "peal" the skin off of toads, or at least leave the toxic parotoid glands behind. Many mustelids are tolerant of amphibian toxins. *Mephitis mephitis, Mustela vison, Mustela frenata,* and *Taxidea taxus* are common throughout the Laramie River Basin.

The observed mortality from depredation suggests that more than 20% of the adult population of this endangered toad was lost in a single event, but this estimate is based only on observed depredation of the marked animals. We have no idea how many unmarked toads may have been lost as there would be no trace of the kills. The vulnerability of this population prior to hibernation due to their aggregative behavior indicates that predator control may become an important tool in their management, at least until their numbers increase sufficiently to sustain such losses.

LINDZEY** (e-mail: flindzey@uwyo.edu), Department of Zoology and Physiology, University of Wyoming, Wyoming Cooperative Fish and Wildlife Research Unit, P.O. Box 3166, Laramie, Wyoming 82071, USA.

BUFO MICROSCAPHUS (Arizona Toad). **REPRODUCTION**. Krupa (1988. Copeia 1988:800–802) provided the clearest evidence that the basket method employed by *Bufo cognatus* maximizes fertilization efficiency in toads. Both Krupa and Miller (for *B. americanus*) described the basket as a space formed when the clasping male "...hooks his feet between the female's hind limbs, thus forming a basket between the feet and the legs of the male and the legs and body of the female" (Miller 1909. Amer. Nat. 43:641–668). However, they did not mention the importance of the male's feet in catching and holding the eggs, as for example in *Litoria verreauxi* (Antis 1976. Trans. Royal Soc. S. Australia 100:193–202) where the male "lowered his vent towards the eggs and cupped his feet around, so holding them....the sides of the male then undulated and his feet moved up and down in a brief fanning motion over the eggs." We observed and videotaped breeding in *B. microscaphus* (Gergus 1988. Herpetologica 54:317–325) along the Beaver Dam Wash at Lytle Preserve in southwestern Utah, USA, 2024 h on 16 March 1999. Ambient air temperature was 9°C and water temperature was 12°C. Clasping male *B. microscaphus* not only assumed a basket position but also used the tops of their feet to cradle the emerging eggs, pulling them up against the vent while fertilizing them. Undulations near the males' cloacas also occurred at this time. Fertilization behavior is stereotyped, each episode involving a few hundred eggs extruded by the female. The behavior can be subdivided into: 1) female ventroflexing—the clasped female extends her legs backwards while forming a concavity with her back; 2) feet-dipping—the clasping male moves his feet from the top of the female's thighs to between her extended legs just below her cloaca; 3) egg extrusion—the male catches the extruding eggs with the tops of this feet and toes and pulls them up towards his cloaca; rhythmic contractions of the muscles surrounding the male's coccyx occur at this time; 4) foot sagging—the male's feet and toes relax and hang slightly away from the female's cloaca; 5) female resumes preventroflexing posture—the female arches her back and flexes her legs into the normal z-shaped amplexus position; and 6) male drops eggs and places his feet on the tops of the female's thighs. From the time the female ventroflexed to alert the male that she was about to extrude eggs to the time when she resumed a normal posture and he placed his feet back on top of her thighs, three episodes of fertilization took 42 sec, 75 sec, and 52 sec. A single female produces an average of 4500 eggs per clutch (Blair 1955. Amer. Mus. Novitates 1722:1–38). Thus, a minimum time for the female to extrude all of her eggs (e.g., 300 per 42 sec fertilization episode) is about 10.5 h, if no delays or pauses occur between these episodes. However, delays between episodes of fertilization do occur and the pair may remain clasped for many more hours.

An annotated videotape of the basket posture for amplexing *B. microscaphus* can be seen at www.li.suu.edu/basket/. A copy of the tape has been deposited with Dr. Jack Sites in the herpetology collections of the Monte Bean Natural History Museum, Brigham Young University. We thank the Monte Bean Museum of Natural History and the Utah Division of Wildlife Resources for permission to study toads at Lytle Preserve.

BUFO PUNCTATUS (Red-spotted Toad). **PREDATION**. Because of their short duration, temporary pools usually contain few predators of larval anurans compared to more permanent habitats (Woodward 1983. Ecology 64:1549–1555). However, water scavenger beetles (Hydrophilidae) typically have an aquatic larval phase of rather brief duration (Archangelsky 1997. Bull. Ohio Biol. Surv., New Ser. 12[1]:1–207), giving this group of predators the opportunity to exploit larval anurans in temporary pools. On 24 June 1999, pools along the intermittent stream in No Thoroughfare Canyon, Colorado National Monument, Colorado, USA, contained

various combinations of *Bufo punctatus*, *Hyla arenicolor*, and *Spea intermontana* tadpoles. No arthropods have been reported as preying on tadpoles of these species (e.g., Hammerson 1999. Amphibians and Reptiles in Colorado. 2nd ed. University Press of Colorado). Most of the pools with tadpoles also contained water scavenger beetle larvae, *Hydrochara lineata* (LeConte). The *S. intermontana* tadpoles had grown to sufficiently large sizes (50–70 mm total length) that they were unlikely to be subject to predation by the insect larvae. However, most tadpoles of other species were much smaller (total length 28 mm). One very small, shallow pool (ca. 0.3 x 0.6 m) contained six *Hydrochara* larvae and three *H. arenicolor* tadpoles sufficiently small to be at risk. At a larger pool, one of the larval insects had captured a *B. punctatus* tadpole and was consuming it by the shoreline.

BUFO TERRESTRIS (Southern Toad). **MAXIMUM SIZE**. The maximum body size reported for *Bufo terrestris* is 113 mm SVL (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed., Houghton Mifflin Co. Boston, Massachusetts, 450 pp.). Here, I report on the measurements of a larger individual. A female was captured on the rainy night of 9 December 1999 in Florida, Miami-Dade County, Everglades National Park (ENP), Royal Palm Hammock Road, immediately north of Royal Palm Hammock. The female (Everglades National Park EVER 308341), frozen then thawed, measured 123.8 mm SVL. Her gape measured 49.6 mm, and she weighed 134.4 g without her digestive tract. Her stomach contained the remains of a freshly eaten millipede of 90 mm. After one week in formalin, she measured 121.9 mm SVL. As noted by Duellman and Schwartz (1958. Bull. Florida State Mus., Biol. Sci. 3:181–324), large females of *B. terrestris* exceeding 100 mm SVL are not rare in southern Florida. In that regard, from a series of 129 females I collected from ENP during 1995–1999, 16.3% exceeded 100 mm SVL and 54.3% exceeded the 41–75 mm SVL reported for this species (Conant and Collins *op. cit.*). The possibility of regional distinction in female body size of *B. terrestris* is an interesting problem in an otherwise poorly studied species.

DENDROBATES AURATUS (Green Poison Frog). **REFUGE USE**. Amphibians that experience dry conditions have developed many desiccation avoidance strategies, including seasonal dormancy and cocoon building (Pough et al. 1998. Herpetology. Prentice-Hall, Inc. New Jersey). In areas with shorter, less predictable dry periods, behavioral modifications may be sufficient for survival. For example, on days without rain, Panamanian *Dendrobates auratus* restrict activity to the cooler hours of the day. The question of how these frogs survive exceptionally long periods of extreme dryness will be addressed here based on observations made on Taboga Island, Republic of Panama. The El Niño of 1997–98 resulted in a short wet season followed by a longer and more severe dry season than usual (Meteorological and Hydrological Branch of the Panama Canal Commission). On 23 April 1998, work began on a population of *Dendrobates auratus* that was abundant in 1996. The forest was extremely dry and there was a pungent smell of smoke from fires that had burned through the leaf litter. There was no dendrobatid activity at sites where there had previously been many frogs. Eventually six *D. auratus* were observed in a boulder crevice in the dry streambed of the Quebrada del Pueblo. Approaching these frogs, one of us (HMG) stepped into a deep depression full of leaf litter directly in front of the crevice. Suddenly frogs started coming out of the leaf litter and hopping away. Seventeen adult and one juvenile *D. auratus* were caught, as well as two *Physalaemus pustulosus* adults. Many of the frogs that went far into nearby rock crevices were not caught, but about 40 frogs are estimated to have been in the 85-cm-wide depression, beneath 55 cm of leaf litter. The soil under the leaf litter was damp to the touch and the leaves directly above the soil moist. Subsequent observations showed that this was one of the places where the mostly subterranean stream would come above ground and form a pool after heavy rainfall. Territorial behavior appeared to have been suspended so these frogs could aggregate in the only area where any moisture could be found. On 27 April, the frogs had dispersed and were moving about the forest. Calling intensity was high as well as aggressive interactions. With the onset of the wet season, territories were being reestablished and defended. One of the frogs caught in the streambed refuge was recaptured a year later 75 m away, indicating that animals may have to travel some distance to escape desiccation. The effect of the long dry season on the population size is unknown, as censusing was not done prior to 1998 in this area. There was mortality probably attributable to desiccation as two *D. auratus* carcasses were found in the leaf litter of the refuge on 27 April. One animal was in advanced decomposition, so may have died before the disturbance of the refuge, while the other animal was fresher but was not one of the animals captured on 23 April. As *D. auratus* is a small frog (SVL <33 mm), carcasses in the leaf litter may have been missed. The largest amphibian in the area, *Bufo marinus*, is harder to miss. Fourteen *B. marinus* skeletons were found in a 6-m stretch of streambed 100 m above the refuge. Another five skeletons were found in <1 m of trail next to this part of the streambed. Pelvic girdles were counted as the skeletons of many individuals were mixed together. The bones were picked clean except for the parotoid glands that were left intact. It is not uncommon in the dry season to find a few *Bufo marinus* skeletons (K. Summers, pers. comm.), but the high number indicates that toad mortality was substantial and this may have also been the case for the *D. auratus*. The populations of *D. auratus* and *B. marinus* appeared to be thriving in 1999. A large protected forest reserve such as that on Taboga may have the necessary microhabitats and large amphibian population sizes necessary to buffer against unusual climatic conditions such as those experienced during El Niño events.

HMG thanks A. S. Rand and K. Summers for comments and advice, R. Symula for help in the field, S. Paton for meteorologi-

cal data, and the Smithsonian Tropical Research Institute for assistance and logistic support.

HYLA BOANS (Rusty Tree Frog). **DIET**. *Hyla boans* is a large tree frog widely distributed across northern South America. On 18 February 1999 at 0900 h we observed a *Hyla boans* (120 mm SVL) eating a bat (Order Chiroptera) in Parque Nacional Cinaruco-Capanaparo, Rio Cinaruco, Estado Apure, Venezuela (6°33'09"N, 67°24'29"W). The bat was only partially ingested, with the wrists (distal ends of both radiae) protruding out of the mouth of the frog. We did not identify the consumed bat. We are unsure if the frog captured the bat while the bat was flying or roosting, nor are we certain the bat was alive when the frog consumed it. This represents, to our knowledge, the first observation of predation on bats by a tree frog of the genus *Hyla*.

Lee Fitzgerald verified the *Hyla* identification.

LIMNONECTES ANDAMANENSIS (Andaman Paddyfield Frog) x ***L. LIMNOCHARIS*** (Cricket Frog). **WILD HYBRIDS**. *Limnonectes andamanensis* and *L. limnocharis* are distinguished on the basis of a rich reddish-brown patch on the dorsum, presence of dorsolateral dermal folds, and a shagreened (vs. elongated warts) dorsum in *L. andamanensis*, which are lacking in *L. limnocharis* (fide Boulenger 1920. Rec. Indian Mus. 20:1–226; Sarkar 1990. Rec. Zool. Surv. India 86:103–117). Three *Limnonectes* sp. collected from Wandoor (11°36'N and 92°40'E), South Andaman Island, Bay of Bengal, India, show the following characteristics: reddish-orange (in life) or orangish-brown (in ethanol) patch in the sagittal region and two paired blotches of the same color on each side of midbody, no dorsolateral folds; dorsum shagreened (two examples) or warty (one example). An adult male (SVL 36.3 mm; field number MCBT 140087) with paired internal vocal sacs and darkened throat, and two adult females (SVL 43.4 and 38.6 mm, field numbers ID/AN 02 01 and 02 02; all specimens now in the Zoological Survey of India [ZSI, registration numbers pending]) are considered wild hybrids between *L. andamanensis* and *L. limnocharis*. They were collected on 16 August 1997 at the edge of a marsh at the ecotone of a rainforest and mangroves, where much of the natural vegetation had been lost to paddy cultivation and settlement. Active, breeding adults of *L. andamanensis* and *L. limnocharis* were also collected from the site. Hybrids between these two species were previously unreported.

I thank the Andaman and Nicobar Forest Department for permission to conduct studies on these islands, the Andaman and Nicobar Islands Environmental Team, and Fauna and Flora International for support through a grant from the Darwin Initiative for the Survival of Species. I also thank Harry Andrews, Manish Chandy, and John Saw for logistic support.

RANA MUSCOSA (Mountain Yellow-legged Frog). **EGG PREDATION**. Tadpoles of *Rana muscosa* were seen feeding on conspecific egg masses in Kings Canyon National Park, Fresno County, California, USA (36°49'30"N 118°25'45"W; 3360 m elev.). Between 24–30 June 1999, a small pond (20 m x 20 m; 1.5 m deep) and outlet stream were checked daily for egg masses. During that period, 136 egg masses were laid, marked with small PVC tubes, and examined daily until hatching. One hundred and one egg masses were laid in the pond and 35 were laid in the outlet stream. *Rana muscosa* tadpoles can take 2–4 years to metamorphose (Zweifel 1955. Univ. California Publ. Zool. 54:207–292), and this pond contained 400–800 second-year tadpoles (28–32 mm body length). Soon after egg laying was completed (1 July 1999), the adult frogs left the immediate breeding area. Over the next four days, tadpoles were concentrated among the egg masses laid in the pond and were seen feeding on eggs (Fig. 1). The tadpoles completely consumed 100 of 101 egg masses laid in the pond. In the outlet stream, 33 egg masses survived to hatching and two became exposed and desiccated. In 1998, tadpoles consumed 63 of 110 egg masses laid in the same pond. In 1999, the single surviving egg mass was 4.5 m east of the outlet and 3.45 m (shoreline length) from the nearest egg mass. We searched the pond thoroughly for newly hatched tadpoles (5–9 July 1999) and never counted more than 25 individuals of this size class (2–4 mm body length). Second-year tadpoles were photographed swallowing eggs with viable embryos. Five second-year tadpoles were collected on 5 July 1999 and preserved in formalin. All five

FIG. 1. Second-year *Rana muscosa* tadpole feeding on conspecific egg

tadpoles contained eggs in their intestinal tracts. I conclude that second-year *R. muscosa* tadpoles are significant predators on conspecific eggs in certain habitats.

RANA UTRICULARIA (Southern Leopard Frog). **PREDATION**. On 11 September 1999 at 0130 h, a barn owl, (*Tyto alba*) was observed foraging on *Rana utricularia* on Country Rd. 84 ca. 6.4 km northwest of Fayetteville, Arkansas, USA (T17N, R31W, NW1/4 Sec 36). The owl was observed to fly down to the paved road and pick up a frog, and then fly away and alight on the top of a nearby telephone pole. After ca. 10 min, the barn owl again landed on the road but was flushed by a car. The owl may have been trying to feed on frogs as there were 3–4 DOR *R. utricularia* on this section of the road. It is known that some species of owls feed on amphibians (Cook 1992. Kingbird 42:84) but most of these observations were reported from pellet analysis (Marti 1991. Barn Owl. *In* Birds of North America No. 1; Jedrzejewski 1994. J. Avian Biol. 25:308–318). To my knowledge, this is the first observation of a barn owl feeding on amphibians and the first report of *R. utricularia* as a prey item. Nero (1986. Blue Jay 44:189–190) provided evidence that great gray owls (*Strix nebulosa*) utilize roads as feeding sites in Manitoba's Interlake Region. Therefore, the use of roads as foraging sites for owls may be a frequent occurrence, but due to the nocturnal behavior of owls and amphibians it is rarely observed.

SCINAX FUSCOMARGINATUS (NCN). **PREDATION**. The attack on amphibians by blood-sucking leeches is common, mainly on aquatic species or those that enter the water to breed (Duellman and Trueb 1986. Biology of Amphibians. McGraw Hill. New York 670 pp.), like *Bufo paracnemis* and *Leptodactylus ocellatus* (A. Sebben, pers. comm.). In most cases however, these attacks are temporary and likely do not drastically interfere with the fitness of the individual (Duellman and Trueb 1986, *op. cit.*).

Here we present an observation of amphibian death caused by the attack of the blood-sucking leech *Oxyptychus brasiliensis* on an adult male *Scinax fuscomarginatus*, an abundant treefrog in wet grasslands in the Cerrado. On 22 December 1998, several adult male *S. fuscomarginatus* were seen calling on an aquatic Cyperaceae, in a little dam in Pirenópolis, Goiás state, Brazil (15°50'S, 48°58'W). At 0100 h we found an adult male *S. fuscomarginatus* (SVL 21.3 mm; Laboratory of Animal Physiology, Universidade de Brasília, UnB 2117) on a leaf tip, 15 cm above the water, with a blood-sucking leech attached on its left flank, close to the arm. When disturbed, the leech released the treefrog with lateral movements and fell into the water, where it was captured. The treefrog showed a circular skin injury 1.77 mm in diameter. An autopsy revealed a deep injury, and consumption of tissues of the left lung. Measurements of the leech (retracted): 12.0 mm total length; 5.38 mm total width; 2.7 mm oral sucker width.

We are grateful to Guarino Colli and Edson Zerbini for critical reading, Antonio Sebben for helpful comments, and Mark Siddal for the identification of leeches. We also thank Bárbara Fonseca and Vívian Braz, who gave their blood for this work.

CEP 70.910-900 (e-mail: adriangarda@hotmail.com).

SCINAX NASICUS (NCN). **HABITAT**. A population of *Scinax nasicus* was studied in Sauce Viejo, Santa Fe town suburban area (Santa Fe, Argentina), from 10 February to 4 April 1996. Six hundred and ninety-seven observations of *S. nasicus* activity were recorded in houses and surrounding habitats.

Individual counts in three windows (1.2 x 1.6 m) with different light intensity (A:5O Ev [lux], B: 83.33 Ev and C: 166.66 Ev) were conducted each day (22–24 h). Climatic data were obtained from EEA-INTA Paraná Meteorological Station.

The proportions of frogs from each different light intensity were tested with the Multiple Proportions Test (Zar 1996. Biostatistical Analysis. Prentice Hall, New Jersey, 662 pp.). The temporal distribution of the number of frogs in different windows was tested with the G test (Sokal and Rohlf 1979. Biometría. Blumé, Madrid, 830 pp.). *Scinax nasicus* activity relative to environmental variables was analyzed through the Conformity rate (h^2). During the day, frogs were found in wet shelters near water sources (reservoirs, fountains tanks, bathrooms, closets, cocks, pipes, drains). At night, the frogs left these refuges and congregated at the windows where arthropods were attracted by the light.

The numbers of frogs at the windows with the greatest light intensity was significant ($c^2 = 46.2$; $p < 0.05$). Temporal distribution of frogs showed significant differences between windows A and B (G: 0.89; $p < 0.05$), A and C (G: 0.88; $p < 0.05$), and B and C (G: 0.77; $p < 0.05$). Frog activity increased when the temperature (h^2: 0.87; $p < 0.05$), relative humidity (h^2: 0.71; $p < 0.05$), and rainfall (h^2: 0.60; $p < 0.05$) increased. A clear trend to use the windows with the greatest intensity was observed. The waste-water drainage systems and the local distribution of human dwellings likely provides refuges for *S. nasicus* during periods of dry conditions. These observations may help explain the propensity of *S. nasicus* to colonize urban areas, as *S. nasicus* is one of the few frogs that cohabit with man in large neotropical areas.

TESTUDINES

CHELYDRA SERPENTINA OSCEOLA (Florida Snapping Turtle) **REPRODUCTION**. The production of two or more clutches per season remains undocumented in *Chelydra* (Iverson et al. 1997. Herpetologica 53:96–117) and clearly is not supported in one population examined by dissection of female reproductive tracts (White and Murphy 1973. Herpetologica 29:240–246). Here, I present data from the dissection of reproductive tracts and from records of nesting in captivity in *Chelydra s. osceola*. These data support the possibilities, suggested more than 20 years ago, that *C. s. osceola* lays multiple clutches per season and has early annual onset of the nesting season (see Ewert 1976. Herpetologica 32:150–156; Moll 1979. *In* Harless and Morlock [eds.], Turtles: Perspectives and Research, pp. 305–331. Wiley, New York, New York).

TABLE 1. Attributes of the reproductive tracts of eight female *Chelydra serpentina osceola* collected in southern Dade Co., Florida.

Date of Capture	Date of Dissection	Sets of Ovarian Corpora Lutea[1]	Oviductal Eggs	Enlarged Ovarian Follicles[2]
3 March 1973	19 March	11	0	8
3 March 1973	24 March	11	11	15
4 March 1973	26 March	18	18	12
10 March 1973	27 March	13, 13	13	5
10 March 1973	30 March	10, 13	13	13
11 March 1973	20 April	10, 7	7	8
21 March 1979	28 March	9, 10, 8	8	0
21 March 1979	29 March	8, 8, 11	11	3

[1] Counts list the oldest set first (measuring 2.0–2.8 mm diam, if oldest of 3 sets), then the next oldest set (4.3–5.7 mm diam, if penultimate set), then the most recent set (6.5–10.5 mm diam).
[2] Only preovulatory sets (18–23 mm diam) are listed. (Occasionally also present: follicles at 15–17.5 mm diam).

Table 1 itemizes elements of the reproductive tracts of eight females collected in southern Dade Co., Florida, USA (2–4 km S to SW of Florida City; 25°25'N, 80°30'W). I palpated each female on the day of capture and felt shelled eggs in five of the six females collected in 1973 and in both females from 1979. The number of most recent corpora lutea equalled the numbers of eggs in both oviducts in the seven individuals with eggs. Two females had three sets of corpora lutea, and three females had just one set. Six females contained enlarged ovarian follicles. One female (collected on 11 March 1973) had two sets of enlarged follicles and could have ovulated two more clutches (8 eggs from pre-ovulatory follicles shown in Table 1 and 7 eggs from enlarged follicles, 15–17 mm diameter, not shown in in Table 1). Combining the counts of sets of corpora lutea and the counts of sets of enlarged follicles (for justification see Moll *op. cit.*) indicates the production of two clutches by three females, three clutches by four females, and possibly, four clutches by two females (10, 7, 8, and 7 eggs from the female collected on 11 March 1973; and 8, 8, 11, and 3 eggs from the female collected on 21 March 1979). Given an estimate of maximum productivity of three clutches per season, these eight females could have produced an average of 27.6 (range 19–36) eggs per female per year.

Two females provided data on production of multiple clutches in captivity. These females were housed in plastic trash containers and fed a highly fortified ground beef and commercial fish diet. A nesting substrate of damp riverine sand was provided in an additional trash bin. When the females were gravid, they were rotated ca. daily between the sand environment and their home container until they had nested. One female, collected as an adult from Dade Co., Florida, mated with a male from Highlands Co., Florida and produced a clutch of five normal eggs on 17 February 1998, and another clutch of seven normal eggs 74 days later on 22 May 1998. Another female, hatched from one of the eggs collected in 1973, matured in captivity and also mated with the male from Highlands Co. Her dates of laying (and egg counts) were 5 August 1990 (8 eggs), 9 September 1990 (11); then, 16 January 1992 (8), 25 February 1992 (10); and then, 23 October 1997 (9), 8 January 1998 (8), and 16 February 1998 (12). None of these clutches contained overmature eggs, an indicator of overlong egg retention that could implicate the conditions in captivity as too abnormal to allow inference on natural history. Additionally, most or all of the eggs in each clutch were fertile and were allowed to hatch. The three shortest internesting intervals estimated from these data are 35, 39, and 40 days. If these intervals are assumed to approximate the shortest ones occurring in the wild, the two gravid females containing their second clutches when collected on 10 March 1973 (Table 1) should have laid their first clutches of the 1972–1973 season during early February, if not before.

I was staying at the Archbold Biological Station (James N. Layne, Director) when I collected the turtles during 1973. Barb Henderson helped rear the one female from hatchling to adult. I thank Craig E. Nelson for helping in many ways. Portions of the dissected females have been deposited at the Carnegie Museum of Natural History, Pittsburgh (CM 86948, 86980–84, 87215–16).

LACERTILIA

AMEIVA BIFRONTATA (Visure Verde, Guaripete). **CANNIBALISM.** The stomach of an adult specimen of *Ameiva bifrontata* (90.4 mm SVL) collected from western Paraguaná Peninsula, State of Falcón, Venezuela, was found to contain the almost intact body of a conspecific juvenile (42.0 mm SVL). Traces of digestion were visible only in the distal portion of the tail. No previous report of cannibalism has been reported in this species (Roze 1964. Mem. Soc. Cienc. Nat. La Salle 24:209–210). The adult and juvenile specimens were catalogued in the Colección Herpetológica Paraguaná Regional del Centro de Investigaciones en Ecología y Zonas Áridas, Universidad Francisco de Miranda, as CIEZAH 989 and CIEZAH 990 respectively.

Submitted by **ABRAHAM MIJARES-URRUTIA**, Centro de Investigaciones en Ecología y Zonas Áridas (CIEZA), Universidad Francisco de Miranda, Apartado 7559, Santa Ana de Coro 4101-A, Venezuela (email: amijares@funflc.org.ve), **LILIMAR OSPINO, ALIXA PARTIDA, EVELÍN PEÑA,** and **YELITZA VALBUENA**, Centro de Ciencias, Unidad Educativa Mariano de Talavera, Punto Fijo, Venezuela.

ANOLIS CONSPERSUS (Grand Cayman Blue-Throated Anole). **NECTIVORY.** Nectivory or possible nectivory has been reported in *Anolis carolinensis* (Himes 1998. Herpetol. Rev. 29:236; Liner 1996. Herpetol. Rev. 27:78; T. S. Campbell and C. Bleazy, pers. comm.) and in *A. stratulus* (Perry and Lazell 1997. Herpetol. Rev. 28:150–151). On 31 May 1990, two of us (ACE and GPG) observed (and photographed) a single adult male *A. conspersus lewisi* (Eastern Grand Cayman Blue-Throated Anole) lapping fluid from the flowers of a wild banana orchid, *Schomburgkia thomsoniana* var. *thomsoniana* (Orchidaceae). The orchid was epiphytic on the trunk of a small tree (trunk diam < 10 cm) ca. 1.5 m above the ground under a relatively open canopy along a trail ca. 50 m north of Farm Road near its junction with Quarry Road on the eastern end of the island of Grand Cayman, British West Indies. The lizard moved out the long peduncles to reach the flowers and, often hanging head-down, inserted its head into the flowers and/or lapped the tips of the petals. It was also observed licking the sepals. The lizard was observed to tongue-wipe its lips after visiting a flower. Other species of *Schomburgkia* are known to have extrafloral nectaries associated with the sepals, but it is not known whether they are present in *S. thomsoniana* (Robert L. Dressler, pers. comm.). Extrafloral nectaries are known to attract ants, but we noted no insects on the flowers and sepals of flowers visited by the lizard, and we saw no insects on other flowers in the inflorecence, nor on their sepals. The flowers of this species of orchid open downward and do not, therefore, hold rainwater. Although it is possible that the lizard was lapping water made available by condensation, our observations were made on the afternoon of a sunny, hot (ca. 32°C), and dry day, and it is probable that it was lapping nectar. One of us (FJB) has observed and photographed similar behavior by *A. c. conspersus* (Western Grand Cayman Blue-Throated Anole) in an undisturbed dry thicket of native trees and shrubs among mangroves, 0.5 km NW of Little Salt Creek, West Bay.

The climate on Grand Cayman is classed as semiarid (Dec–Feb), arid (Mar–Apr), or subhumid (May) for six months of the year (Burton 1994. *In* Brunt and Davies [eds.], The Cayman Islands: Natural History and Biogeography, pp. 51–60. Kluwer Academic Publishers, Dordrecht, Netherlands). At least seasonally, in this environment of highly seasonal and episodic precipitation, the water gained by lapping nectar may be more important to the lizards than any energy gained. We have no explanation for our observation of the lizard licking the sepals.

We thank G. Ebanks-Petrie and J. E. Davies, then of the Cayman Islands Mosquito Research and Control Unit, for logistic support and other assistance, and Todd S. Campbell for comments on the manuscript.

BURTON**, National Trust for the Cayman Islands, P.O. Box 31116 SMB, Grand Cayman, Cayman Islands, B.W.I. (e-mail: fjburton@candw.ky).

ANOLIS SAGREI (Brown Anole). **CANNIBALISM.** Intraspecific killing and cannibalism have been reported for many organisms, including reptile species (Fox 1975. Ann. Rev. Ecol. Syst. 6:87–106; Hausfater and Hrdy [eds.] 1984. Infanticide: Comparative and Evolutionary Perspectives. Aldine. New York. 598 pp; Polis. 1981. Ann. Rev. Ecol. Syst. 12:225–251; Polis et al. 1984. Mamm. Rev. 14:187–198). Anoles are not known for cannibalistic tendencies. A commonly-studied species, *Anolis carolinensis*, is not known to engage in infanticide. Only one instance of cannibalism has been reported in *A. carolinensis* (Jenssen 1993. Herpetol. Rev. 24:58–59) and is believed to be an example of social pathology rather than typical behavior (Jenssen et al. 1998. Copeia 1998:774–779). We are not aware of any other published accounts of *Anolis* cannibalism.

We have observed two instances of adult *Anolis sagrei* consuming conspecifics, a hatchling and a juvenile. During a morning in September 1997, KEN and PMR observed an adult *A. sagrei* male (Fig.1) consume a hatchling-sized individual in a suburban setting. The adult moved quickly down a stick towards the ground, captured a prey item and then climbed back up the perch to consume its catch. Upon closer inspection, the prey item was a hatchling *A. sagrei*. On a second occasion (26 February 1998), KEN and AVP observed an adult male *A. sagrei* consume a juvenile male conspecific (SVL 32 mm). In this case, KEN and AVP were capturing, measuring, and releasing *A. sagrei* as part of another study. AVP released a captured individual that was promptly consumed by a larger conspecific.

FIG. 1. Adult male *Anolis sagrei* consuming a hatchling conspecific.

The consumption of young anoles by *A. sagrei* is of particular interest because *A. sagrei* is an introduced species that interacts with the native species *A. carolinensis* in the southeastern United States (Campbell 1996. Herpetol. Rev. 27:155). If *A. sagrei* consume conspecifics, they may also consume juvenile and subadult *A. carolinensis* and influence survivorship in the latter species.

It is unknown whether cannibalism among *A. sagrei* is common. However, our observations suggest that cannibalism may have implications for studies of territoriality and social behavior in this and other species of *Anolis*.

GEKKO GECKO (Tokay Gecko). **PREDATION**. Introduced species may impact native species by directly preying upon them in addition to indirectly competing with them for local resources. This note documents a case of an introduced lizard capturing and ingesting a juvenile indigenous snake. An adult *Gekko gecko* (ca. 26 cm total length) regularly prowls the wall of a building near my home in Alva, Lee County, Florida, USA. While walking past that wall during November 1998, two hours after sunset, I noticed the gecko in its favorite hunting position near an office window. A pass of my flashlight on that evening revealed the gecko clinging above the window, its head aimed downward with something long and slender, about the same length as the gecko's entire body, dangling straight down from its mouth. I couldn't discern what the item was, and I chose to get my camera from the car to record the curious phenomenon, whatever it was, rather than risking frightening the gecko into flight by approaching more closely. I was able to get a shot from a distance of about 4 m away by using a 200mm macro lens before it scurried for cover taking with it the mystery object. The identity of this item was unknown until the film was developed. The resulting photograph (Fig.1) showed that the object was a juvenile corn snake (*Elaphe g. guttata*) of ca. 30 cm total length, its head held firmly in the gecko's jaws. Its limp body suggests that the snake was already dead when I first encountered the situation.

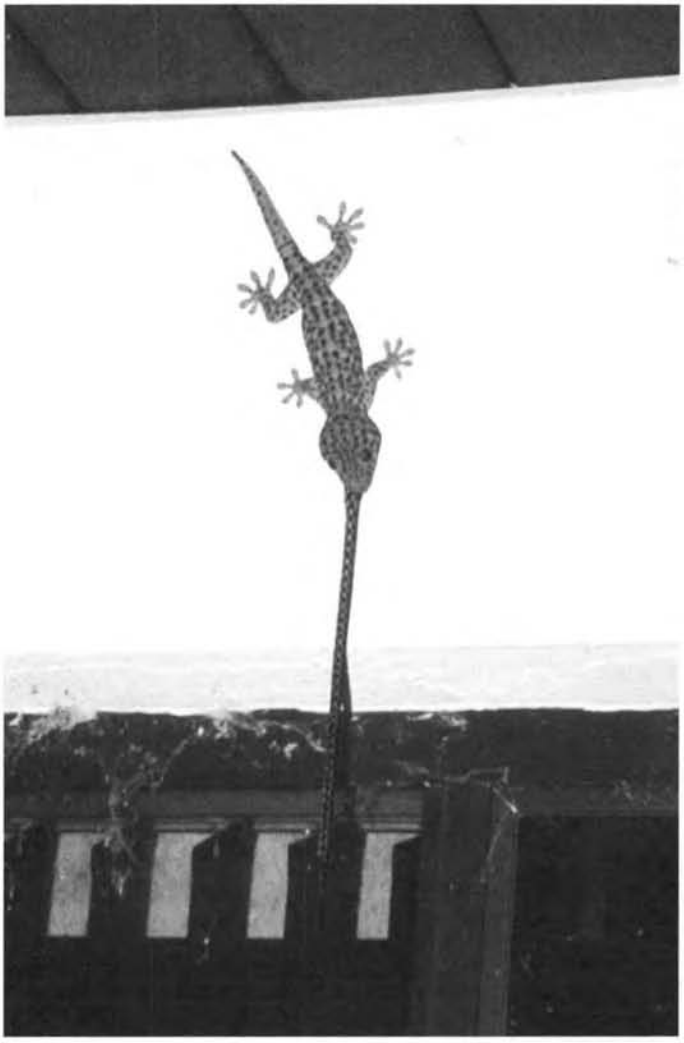

Fig. 1. Adult *Gekko gecko* with juvenile *Elaphe g. guttata* in its jaws.

LIOLAEMUS KOSLOWSKY (NCN). **SAUROPHAGY**. *Liolaemus koslowsky* is a tropidurid lizard found in the intermontane valleys of La Rioja and Catamarca Provinces, northwestern Argentina. The diet of this species has been recently described and is known to include insects and spiders (Aun and Martori 1998. Cuad. Herp. 12[1]:1–9). Here we report an observation of interspecific saurophagy by an adult male *L. koslowsky* on a hatchling *L. pseudoanomalus*. On 29 January 1999, during the course of an ecological study of lizard communities carried out 6 km E Anillaco town (28°49'S, 66°57'W), Castro Barros Department, La Rioja Province, we collected in a bush land site, an adult male *L. koslowsky* (FML 08188, SVL 62 mm, TL 85 mm [tail broken], weight 7.96 g) using a rubber band. We hand-grabbed the lizard and as we squeezed it for a more secure grasp, the tail of another lizard protruded from its mouth. We grabbed the tail and pulled out a complete and dead hatchling of *Liolaemus pseudoanomalus* (FML 08189, SVL 32 mm, TL 43 mm, weight 0.96 g). The stomach contents of the *L. koslowsky* were subsequently examined and found to contain Coleoptera and Orthoptera. Saurophagy has not been previously documented under natural conditions for *Liolaemus* in Argentina.

These two lizard species are common and widespread in this part of the Monte biogeographic region and share similar microhabitats. Thus, predation on hatchlings of *L. pseudanomalus* by adult *L. koslowsky* may be a frequent occurence. Lizard identifications were verified by Fernando Lobo and specimens were deposited in the Herpetological Collection of the Instituto de Herpetología, Fundación Miguel Lillo, San Miguel de Tucumán, Tucumán, República Argentina (FML).

MABUYA MACRORHYNCHA (NCN). **ECTOPARASITES**. During a study of the skink *Mabuya macrorhyncha* at the island of Queimada Grande (24°30'S; 43°42'W), located ca. 33 km off the coast of São Paulo state in southeast Brazil, DV collected eight specimens on 21–22 November 1997 (wet season) and eleven specimens on 30–31 July 1998 (dry season). Three specimens in each year were damaged during collection and will not be considered here. The remaining 13 individuals (five males and eight females) ranged from 57.5 to 77.5 mm SVL. Subsequent examination of the lizards revealed the presence of acarine ectoparasites: all specimens (100%) bore larvae of the trombiculid mite *Eutrombicula* cf. *alfreddugesi* and four of them (30.8%) also

bore larvae of the ixodid tick *Amblyomma rotundatum*. Voucher specimens of *A. rotundatum* were deposited at the collections of the Instituto Butantan (IB 7016–17) and of the Instituto Oswaldo Cruz (IOC 0408 / IXA). The lizards were deposited at the Museu Nacional do Rio de Janeiro (MNRJ 7286–7304).

Chigger mites (larval *E.* cf. *alfreddugesi*) were found associated with the anterior axilllae of all lizards (one individual also bore three mites on the left groin), where scales are small and granular, while ticks were always found attached to the skin between two large scales of the torso. Mean parasite intensity (*sensu* Bush et al. 1997. J. Parasitol. 83:575–583) of *E.* cf. *alfreddugesi* was 26.8 ± 22.5 mites per lizard (range 3–68), and mean intensity per axilla was 15.0 ± 12.0 (range 1–47). All lizards had chigger mites on the left axilla and ten (76.9%) also bore them on the right axilla. Using one-way analyses of variance (ANOVA), we did not find any significant difference in mean intensity of chigger mite infestation between months ($F_{1,11} = 0.15$; $P = 0.71$) nor between sexes of hosts ($F_{1,11} = 0.34$; $P = 0.57$). Chigger mite intensity was not correlated with host SVL ($r = 0.13$; $F_{1,11} = 1.60$; $P = 0.23$). The mean parasite intensity of *A. rotundatum* was 1.25 ± 0.50 (range 1–2), with three lizards bearing a single tick and one bearing two. Ticks were found in the ventral region of all parasitized hosts, with one of them also bearing a tick on the dorsolateral region, near the right groin.

Intensity of infestation of *E.* cf. *alfreddugesi* in the *M. macrorhyncha* population of Queimada Grande was lower than that reported for a mainland coastal population of conspecifics inhabiting a sand-dune habitat in Rio de Janeiro State (mean = 42.6 mites/lizard; Cunha-Barros and Rocha 1995. Oecologia Bras. 1:307–316), perhaps due to a possible lower density of mites on the island than on the mainland. In that population, as in the insular one treated here, ectoparasite intensity does not seem to be correlated with host sex or size (Cunha-Barros and Rocha, *op. cit.*). Unlike our observations in the insular skink population, *E.* cf. *alfreddugesi* infest mainland skinks on various parts of their bodies, though most intensely in the axillary region (Cunha-Barros and Rocha, *op. cit.*). This fact may also be indicative of a lower density of mites on the island.

Amblyomma rotundatum is a common parasite of neotropical snakes, anurans, and tortoises (Amorim and Serra-Freire 1995. Parasitol. al Dia 19:9–19; Aragão 1936. Mem. Inst. Oswaldo Cruz 31:759–843), and has also been recovered from teiid and tropidurid lizards (Amorim and Serra-Freire, *op. cit.*; D. M. Barros-Battesti, pers. comm.). Adults of *A. rotundatum* are known to parasitize the endemic pitviper *Bothrops insularis* at Queimada Grande (Aragão 1936. *op. cit.*; Duarte et al. 1995. Stud. Neotrop. Fauna Environ. 30:1–23). *Mabuya macrorhyncha* represents a new host record for *A. rotundatum*.
